Opening Up the Gamma Ray Sky

LIKE A LIGHTHOUSE BLINKING IN THE NIGHT, A pulsar appears to flash periodically as it spins in space, sweeping a double cone of electromagnetic radiation across the sky. Since the discovery of the first pulsar 4 decades ago, astronomers have detected hundreds more of these enigmatic objects from the pulsing radio waves they emit. Now, astronomers have opened a new channel of discovery—the highly energetic gamma ray spectrum—to find pulsars that radio observations could not detect. The advance, part of a torrent of recent gamma ray observations, is giving researchers an improved understanding of how pulsars work, along with a rich haul of new pulsars that could help in the quest to detect gravitational waves.

The findings come from the Fermi Gamma-ray Space Telescope, which has been mapping the gamma ray universe since it was launched by NASA in June 2008. Combing through data the telescope collected in its first few months, an international team discovered 16 new pulsars; strong gamma ray pulsations from eight

previously known pulsars with spin times of milliseconds, proving that these objects pulse brightly at gamma wavelengths as well as in the radio range; and high-energy gamma rays from the globular cluster 47 Tucanae indicating that the cluster harbors up to 60 millisecond pulsars.

Those Fermi results might be just the beginning. Armed with their new knowledge of pulsar behavior, researchers are checking whether some of the unidentified gamma ray sources Fermi has detected might be pulsars. In November alone, teams of astronomers in the United States and France discovered five new millisecond pulsars by training ground-based radio telescopes on candidate objects Fermi had pointed out—a much more targeted search technique than scanning the sky blindly with ground-based radio telescopes.

Gamma ray beams of pulsars are believed to be wider than their radio beams, so in principle a space-based gamma ray telescope should be more likely to encounter and discern a pulsar's sweep than a radio telescope on Earth is. However, Fermi's forerunner—

from www.sciencemag.org on December 22, 2009

the Compton Gamma Ray Observatory, which flew from 1991 to 2000—did not have much luck finding these objects. What has made the difference is Fermi's high sensitivity, which enables it to detect pulsations that would have been too faint for Compton.

Already, the discoveries are shedding new light on the physics of pulsars. Researchers

Breakthrough of the Year was the reconstruction of the 4.4-million-year-old *Ardipithecus ramidus* skeleton

production
(Particle colliders)

scattering
(Direct detection)

Neutralino WIMPs

Assume χ present in the galactic halo

- χ is its own antiparticle \Rightarrow can annihilate in galactic halo producing gamma-rays, antiprotons, positrons....
- Antimatter not produced in large quantities through standard processes (secondary production through $p + p \rightarrow \text{anti } p + X$)
- So, any extra contribution from exotic sources ($\chi \chi$ annihilation) is an interesting signature
- ie: $\chi \chi \rightarrow \text{anti } p + X$
- Produced from (e. g.) $\chi \chi \rightarrow q / g / \text{gauge boson} / \text{Higgs boson}$ and subsequent decay and/ or hadronisation.

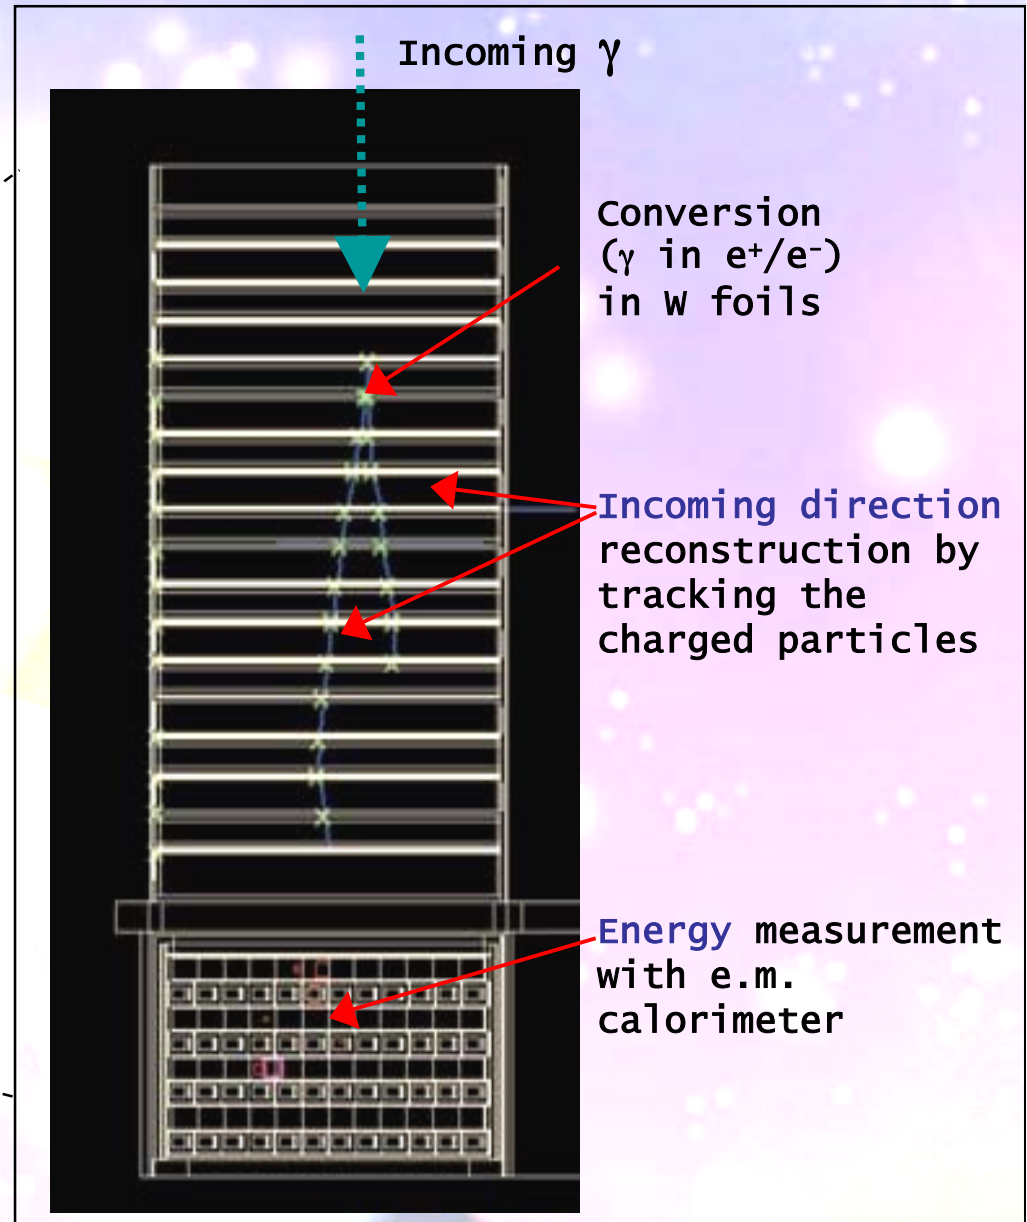

How Fermi LAT detects gamma rays

4 x 4 array of identical towers with:

- Precision Si-strip tracker (TKR)
 - With W converter foils
- Hodoscopic CsI calorimeter (CAL)
- DAQ and Power supply box

An anticoincidence detector around the telescope distinguishes gamma-rays from charged particles

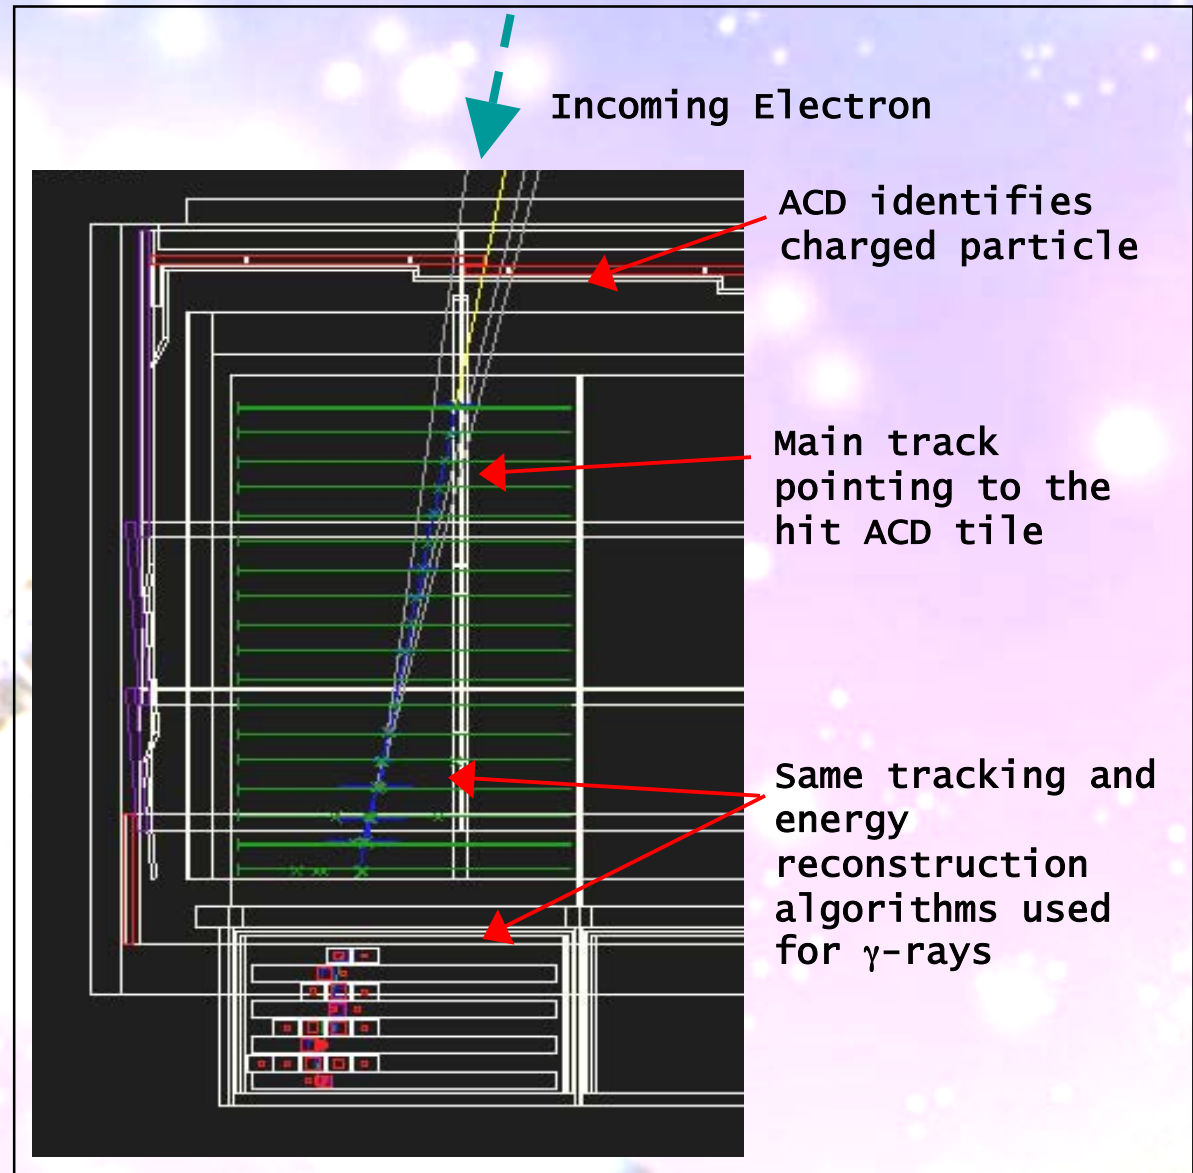

How Fermi LAT detects electrons

Trigger and downlink

- LAT triggers on (almost) every particle that crosses the LAT
 - ~ 2.2 kHz trigger rate
- On board processing removes many charged particles events
 - But keeps events with more than 20 GeV of deposited energy in the CAL
 - ~ 400 Hz downlink rate
- Only ~1 Hz are good γ -rays

Electron identification

- The challenge is identifying the good electrons among the proton background
 - Rejection power of 10^3 - 10^4 required
 - Can not separate electrons from positrons

Event topology

**A candidate electron
(recon energy 844 GeV)**

**A candidate hadron
(raw energy > 800 GeV)**

- TKR: clean main track with extra-clusters very close to the track
- CAL: clean EM shower profile, not fully contained
- ACD: few hits in conjunction with the track

- TKR: small number of extra clusters around main track
- CAL: large and asymmetric shower profile
- ACD: large energy deposit per tile

Fermi-LAT CRE data vs the conventional *pre-Fermi* model

Although the feature @~600 GeV measured by ATIC is not confirmed
Some changes are still needed with respect to the *pre-Fermi* conventional mode

Cosmic Ray Electron propagation models

Model #	D_0 ($cm^2 s^{-1}$)	δ	z_h (kpc)	γ_0	N_{e^-} ($m^{-2} s^{-1} sr^{-1} GeV^{-1}$)	γ_0^p
0	3.6×10^{28}	0.33	4	2.54	1.3×10^{-4}	2.42
1	3.6×10^{28}	0.33	4	2.42	1.3×10^{-4}	2.42
2	1.3×10^{28}	0.60	4	2.33	1.3×10^{-4}	2.1

Models 0 and 1 account for CR re-acceleration in the ISM, while 2 is a plain-diffusion model. All models assume $\gamma_0 = 1.6$ below 4 GeV.

“Conventional” model with injection spectrum 1.60/2.42 (break at 4 GeV)

new : Fermi Electron + Positron spectrum

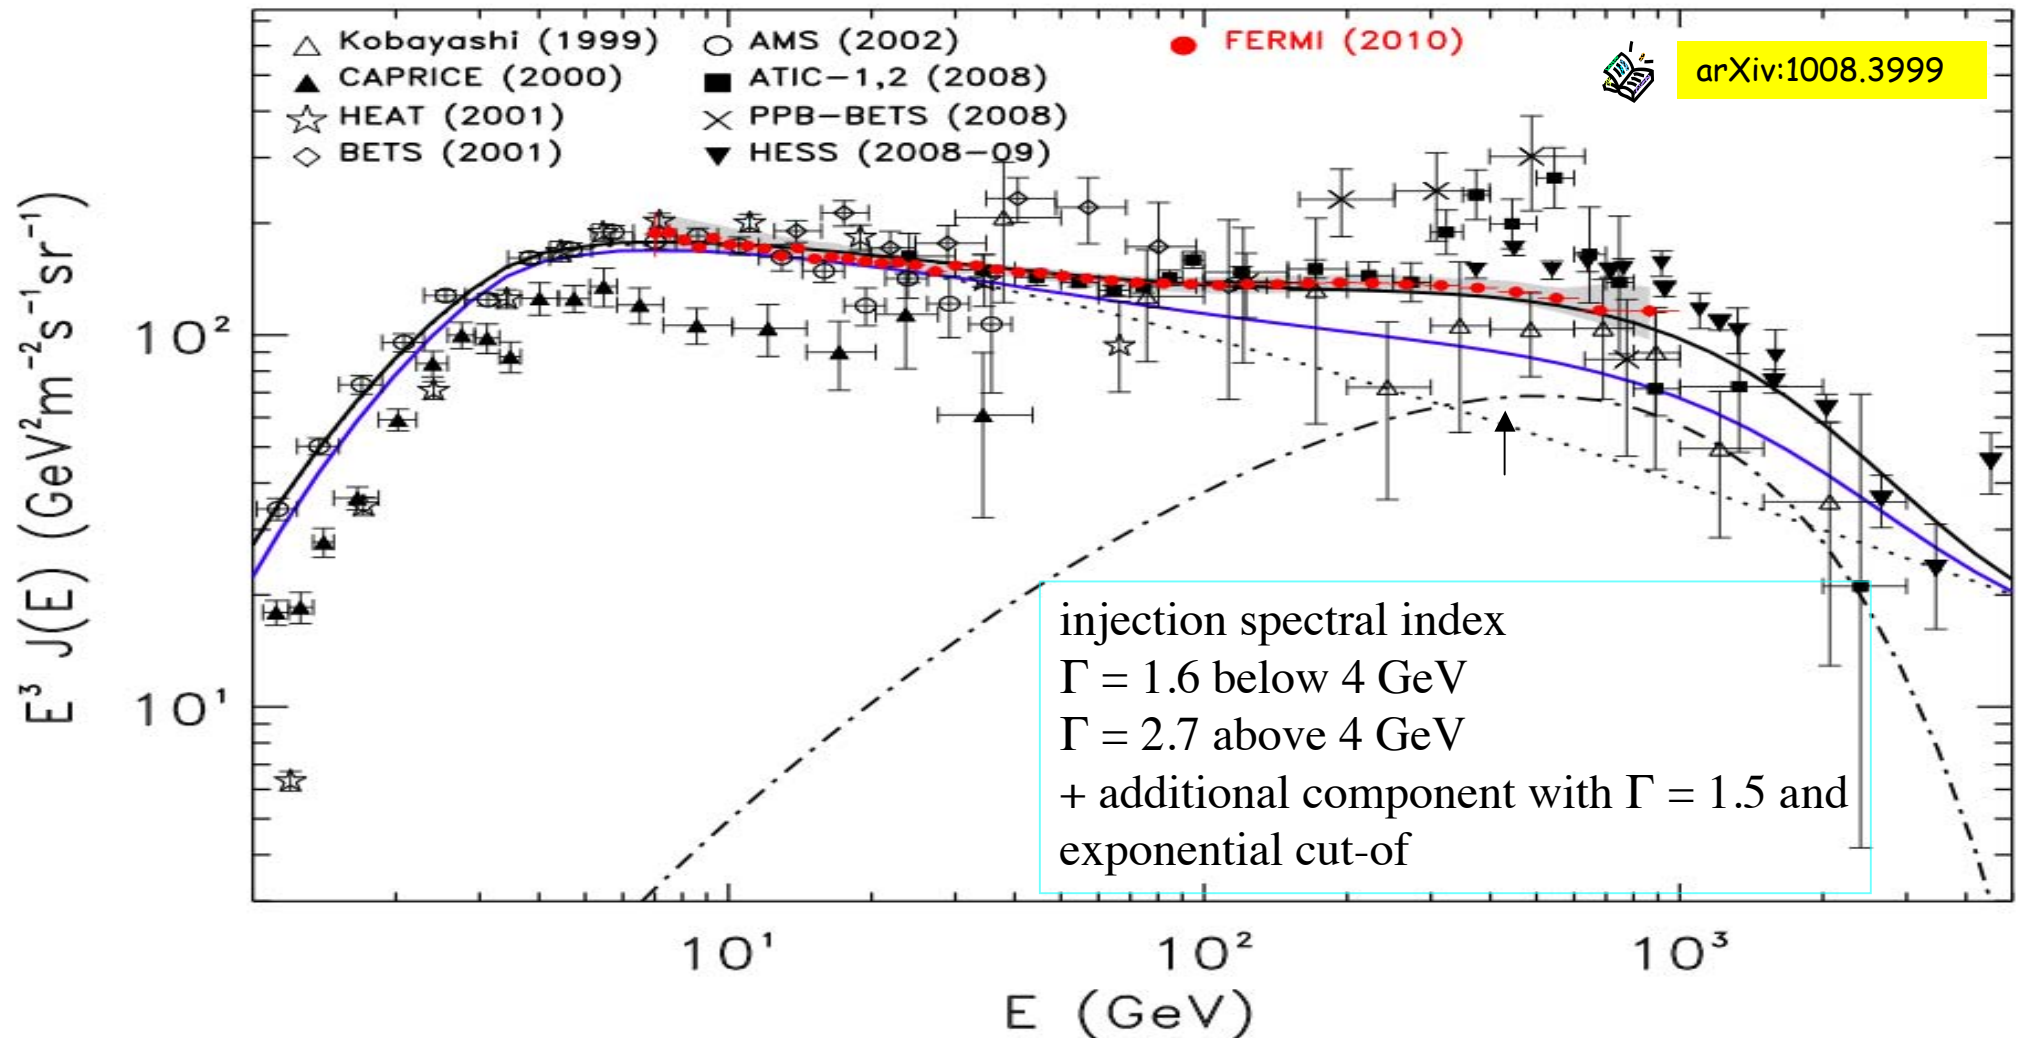

Extended Energy Range (7 GeV – 1 TeV) One year statistics (8M evts)

New Fermi-LAT data at low energy

Problems at low energy are confirmed!!!

Electron spectrum and a conventional GALPROP model +...

Hard to get a good fit with a single-component diffusive model

Good fit possible with an additional high-energy component

If it is an e^+/e^- (e. g. nearby pulsars or dark matter), the Fermi spectrum and Pamela positron fraction can be simultaneously fitted

The CRE spectrum accounting for nearby pulsars ($d < 1$ kpc)

This particular model assumes: 40% e^\pm conversion efficiency for each pulsar
 • pulsar spectral index $\Gamma = 1.7$ $E_{\text{cut}} = 1$ TeV . Delay = 60 kyr

the positron ratio accounting for nearby pulsars ($d < 1$ kpc)

[arXiv:0905.0636]

Pulsars

1. On purely energetic grounds they work (relatively large efficiency)
2. On the basis of the spectrum, it is not clear
 1. The spectra of PWN show relatively flat spectra of pairs at Low energies but we do not understand what it is
 2. The general spectra (acceleration at the termination shock) are too steep

The biggest problem is that of escape of particles from the pulsar

1. Even if acceleration works, pairs have to survive losses
2. And in order to escape they have to cross other two shocks

New Fermi data on pulsars will help to constrain the pulsar models

What if we randomly vary the pulsar parameters relevant for e^+e^- production?

(injection spectrum, e^+e^- production efficiency, PWN “trapping” time)

Under reasonable assumptions, electron/positron emission from pulsars offers a viable interpretation of Fermi CRE data which is also consistent with the HESS and Pamela results.

[arXiv:0905.0636]

65 Gamma-Ray Pulsars, with 24 from blind searches

Pulsars at
1/10th true rate

The Pulsing γ -ray Sky

- New pulsars discovered in a blind search
- Millisecond radio pulsars
- Young radio pulsars
- Pulsars seen by Compton Observatory EGRET instrument

Spectral measurements and emission models

Evidence of γ -ray emission in the outer magnetosphere due to absence of super-exponential cutoff

- Radio and γ -ray fan beams separated
- γ -ray only PSRs

other Astrophysical solution

- Positrons created as secondary products of hadronic interactions inside the sources
- Secondary production takes place in the same region where cosmic rays are being accelerated
- > Therefore secondary positron have a very flat spectrum, which is responsible, after propagation in the Galaxy, for the observed positron excess

Blasi, arXiv:0903.2794

Positrons created as secondary products of hadronic interactions inside the sources (2)

if this is true we should observe a rise in the secondary/primary CR fraction

Lepto-philic Models

here we assume a democratic dark matter pair-annihilation branching ratio into each charged lepton species: 1/3 into e^+e^- , 1/3 into $\mu^+\mu^-$ and 1/3 into $\tau^+\tau^-$. Here too antiprotons are not produced in dark matter pair annihilation.

Cosmic Ray Electrons Anisotropy

More than 1.6 million electron events with energy above 60 GeV have been analyzed on anisotropy

- Upper limit for the dipole anisotropy has been set to 0.5 – 5% depending on the energy
- Upper limit on fractional anisotropic excess ranges from a fraction to about one percent depending on the minimum energy and the anisotropy's angular scale

Distribution of significance, fitted by a Gaussian

Fermi Coll.
Phys. Rev. D accepted
[arXiv:1008.5119]

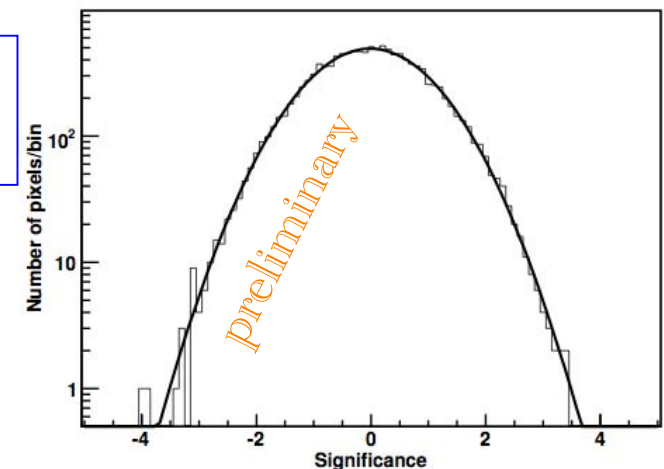

Cosmic Ray Electrons Anisotropy

the levels of anisotropy expected for Vela-like and Monogem-like sources (i.e. sources with similar distances and ages) seem to be higher than the scale of anisotropies excluded by the results
However, it is worth to point out that the model results are affected by large uncertainties related to the choice of the free parameters

Search for Dark Matter in the Galactic Center

- Steep DM profiles \Rightarrow Expect large DM annihilation/decay signal from the GC!
- Good understanding of the astrophysical background is crucial to extract a potential DM signal from this complicated region of the sky:
 - source confusion: energetic sources near to or in the line of sight of the GC
 - diffuse emission modeling: uncertainties on the intensity and spectra of the CRs and distribution of gas and radiation field targets along the line of sight

Fermi LAT Observations of the GC

- Extragalactic Diffuse modelled as an isotropic $+3^\circ$ emission with a template spectrum.
- Red and blue profiles do not include point sources
- The diffuse gamma-ray intensity in the GC region is intense & not dominated by the GC region
- Systematic uncertainties in the GC contribution remain large, interstellar radiation and gas

Preliminary Analysis

7° x 7° Region Of Interest centered at RA=266.46° Dec=-28.97°

- 11 months of data
- events from 400 MeV to 100 GeV
- IRFs Pass6_v3
- Diffuse Class events, converting in the front part of the tracker
- Model of the Galactic Center includes:
- 11 sources from Fermi 1st year Catalog (inside or very near the ROI)
- Galactic and Extragalactic Diffuse Background
- Binned likelihood analysis using the GTLIKE tool, developed by the Fermi/LAT collaboration

Spectrum $(E > 400 \text{ MeV}, 7^\circ \times 7^\circ \text{ region centered on the Galactic Center analyzed with binned likelihood analysis})$

GC Residuals

$7^\circ \times 7^\circ$ region centered on the Galactic Center
11 months of data, $E > 400$ MeV, front-converting events
analyzed with binned likelihood analysis)

- The systematic uncertainty of the effective area (blue area) of the LAT is $\sim 10\%$ at 100 MeV, decreasing to 5% at 560 MeV and increasing to 20% at 10 GeV

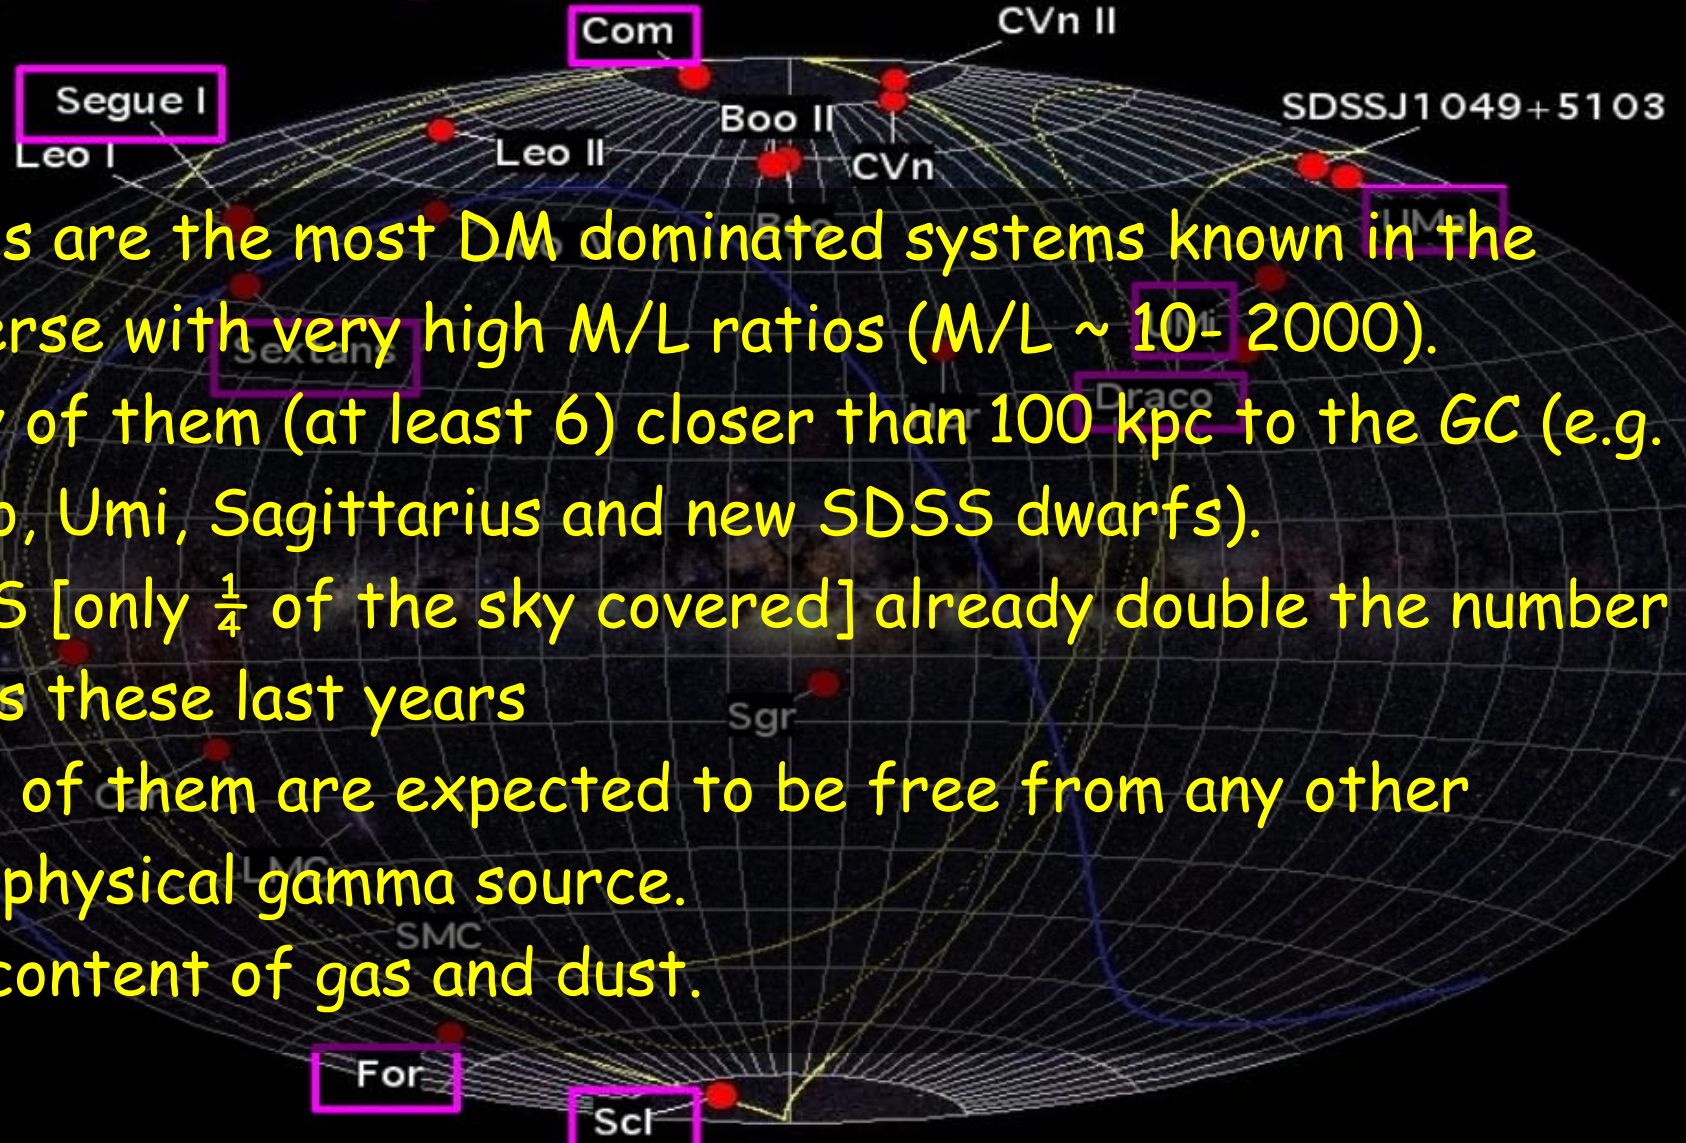

Search for Dark Matter in the Galactic Center

- ➔ Model generally reproduces data well within uncertainties. The model somewhat under-predicts the data in the few GeV range (spatial residuals under investigation)
- ➔ Any attempt to disentangle a potential dark matter signal from the galactic center region requires a detailed understanding of the conventional astrophysics and instrumental effects
- More prosaic explanations must be ruled out before invoking a contribution from dark matter if an excess is found (e.g. modeling of the diffuse emission, unresolved sources,)
- Analysis in progress to updated constraints on annihilation cross section

Dwarf spheroidal galaxies (dSph) : promising targets for DM detection

Dwarf spheroidal galaxies (dSph) : promising targets for DM detection

- 
- dSphs are the most DM dominated systems known in the Universe with very high M/L ratios ($M/L \sim 10 - 2000$).
 - Many of them (at least 6) closer than 100 kpc to the GC (e.g. Draco, Umi, Sagittarius and new SDSS dwarfs).
 - SDSS [only $\frac{1}{4}$ of the sky covered] already double the number of dSphs these last years
 - Most of them are expected to be free from any other astrophysical gamma source.
 - ✓ Low content of gas and dust.

Dwarf Spheroidal Galaxies upper-limits

No detection by Fermi with 11 months of data. 95% flux upper limits are placed for several possible annihilation final states.

Flux upper limits are combined with the DM density inferred by the stellar data^(*) for a subset of 8 dSph (based on quality of stellar data) to extract constraints on $\langle \sigma v \rangle$ vs WIMP mass for specific DM models

Inverse Compton Emission and Diffusion in Dwarfs

- We expect significant IC gamma-ray emission for high mass WIMP models annihilating to leptonic final states.
- The IC flux depends strongly on the uncertain/unknown diffusion of cosmic rays in dwarfs.
- We assume a simple diffusion model similar to what is found for the Milky Way
 $D(E) = D_0 E^{1/3}$ with $D_0 = 10^{28} \text{ cm}^2/\text{s}$
(only galaxy with measurements, scaling to dwarfs ??)

Dwarf Spheroidal Galaxies upper-limits

Exclusion regions

already cutting into interesting parameter space for some WIMP models

Stronger constraints can be derived if IC of electrons and positrons from DM annihilation off of the CMB is included, however diffusion in dwarfs is not known \Rightarrow use bracketing values of diffusion coefficients from cosmic rays in the Milky Way

(*) stellar data from the Keck observatory (by Martinez, Bullock, Kaplinghat)

Search for Spectral Gamma Lines

Conclusion:

The Electron+positron spectrum (CRE) measured by Fermi-LAT is significantly harder than previously thought on the basis of previous data

Adopting the presence of an extra e^+ primary component with ~ 1.5 spectral index and $E_{\text{cut}} \sim 1 \text{ TeV}$ allow to consistently interpret Fermi-LAT CRE data (improving the fit), HESS and PAMELA

Such extra-component can be arise if the secondary production takes place in the same region where cosmic rays are being accelerated (to be tested with future B/C measurements)

- or by **pulsars** for a reasonable choice of relevant parameters (to be tested with future Fermi pulsars measurements)
- or by annihilating **dark matter** for model with $M_{\text{DM}} \approx 1 \text{ TeV}$
- Improved analysis and complementary observations

(CRE anisotropy, spectrum and angular distribution of diffuse γ , DM sources search in γ) are required to possibly discriminate the right scenario.

2nd Conclusion : Gamma

- No discovery (yet)... 😞
- ... however promising constraints on the nature of DM have been placed 😊

(exclusion of a lot of DM models that explain the origin of the Fermi/Pamela lepton excess)

- In addition to increased statistics, better understanding of the astrophysical and instrumental background will improve our ability to reliably extract a potential signal of new physics or set stronger constraints
- Further improvements are anticipated for analysis that benefits from multi-wavelength observations (for example **galactic center**, dwarf spheroidal galaxies and DM satellites)

NEXT FERMI SYMPOSIUM 9-12 May 2011 in Rome

III Fermi Symposium

The 2011 Fermi Symposium is dedicated to results and prospects for scientific exploration of the Universe with the Fermi Gamma-ray Space Telescope and related studies.

Topics include: blazars and other active galactic nuclei, pulsars, gamma-ray bursts, supernova remnants, diffuse gamma radiation, unidentified gamma-ray sources, and searches for dark matter. Multi-wavelength/multi-messenger contributions to these topics are welcome.
