

# Measurements and searches with Decay-At-Rest neutrinos produced at J-PARC MLF

Takasumi Maruyama (KEK)

# Introduction

- Neutrinos produced by Decay-At-Rest (of  $\pi$ ,  $\mu$ , K) are useful tool for the nuclear / particle physics.
  - 0(10) MeV neutrinos are useful to understand the super-nova physics, for example.
  - 0(100) MeV neutrinos are useful to understand the systematic uncertainties of neutrino interactions which are used for the neutrino oscillation measurement.
  - Also useful to search for the short baseline neutrino oscillations.
- They have well known energy due to 0 momentum of parent particles.
- They have well known  $1/r^2$  dependence of neutrino fluxes due to isotopic decays.
- Minus charge parent particles such as  $\pi^-$  are absorbed by nucleus.
- (one disadvantage is the small neutrino flux compared to the horn focused beam).

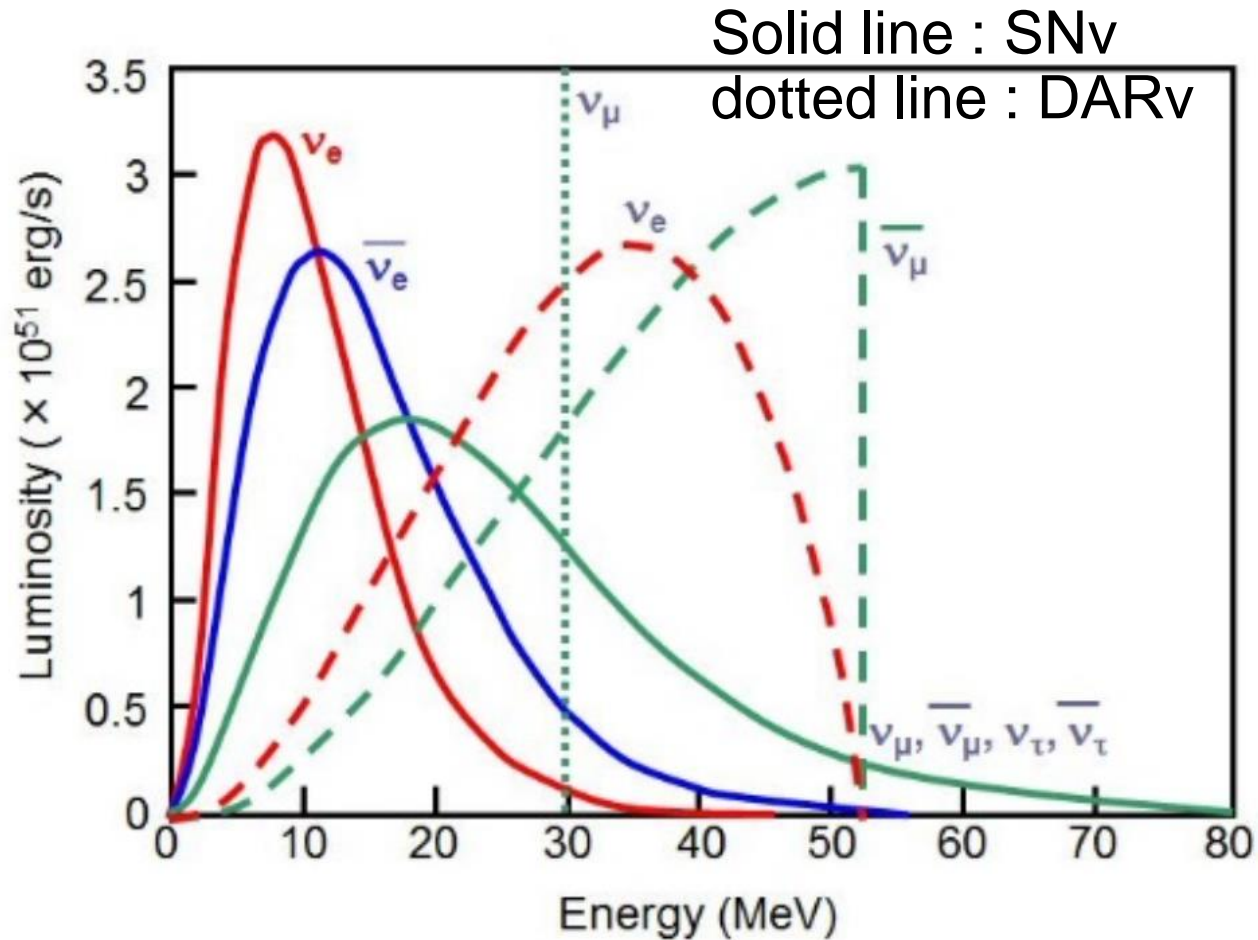

# World DAR sources

Facility	country	Beam	Beam power	Beam energy	Time structure	target
ISIS	UK	Proton Synchrotron (PS)	0.16 MW (@ KARMEN)	0.8 MeV	50Hz (2 bunches)	Ta-D <sub>2</sub> O
SNS	US	PS	~1.7 MW	~1.3 GeV	60Hz (1 bunch)	Liquid Hg
MLF (J-PARC)	Japan	PS	1.0 MW	3.0 GeV	25Hz (2)	Liquid Hg
CSNS	China	PS	0.1 MW	1.6 GeV	25Hz (2)	Ta cladde W
ESS	Europe (Sweden)	Linac	5.0 MW	2.0 GeV	--	W (Tungsten)
Los Alamos	US	Linac + dump	0.64 MW	0.8 GeV	--	H <sub>2</sub> O
Iso-DAR	?	cyclotron + dump				

- Generally, facilities for neutron (not neutrino) spallation source also give the good DAR neutrinos.
- DARs using other accelerators are also available, however duty factor of the Linac case is much worse than PS case. (typically more than 100)
- SNS has a few results on cross sections of the coherent neutrino scattering.

# Example of application : SuperNova(SN)v and DARv

Neutrinos from  $\mu$ -DAR  
have a few tens of MeV ;

-> similar range with SNv

-> Measurements of those DARv  
can also be useful for detection and  
evolution study of SNv

# Example: Measurements of $\nu$ -A cross section

Reaction	Neutrino Source	Accuracy
$^{12}\text{C}(\nu_e, e^-)^{12}\text{N}_{\text{gs}}$	Accelerator DAR $\nu$	~10%
$^{12}\text{C}(\nu_e, e^-)^{12}\text{N}^*$	Accelerator DAR $\nu$	~15%
$^{12}\text{C}(\nu, \nu')^{12}\text{C}(1+1)$	Accelerator DAR $\nu$	~20%
$^{12}\text{C}(\nu_e, e^-)^{13}\text{N}$	Accelerator DAR $\nu$	76%
$^{56}\text{Fe}(\nu_e, e^-)^{56}\text{Co}$	Accelerator DAR $\nu$	37%
$^{71}\text{Ga}(\nu_e, e^-)^{71}\text{Ge}$	RI ( $^{51}\text{Cr}$ )	11%
$^{127}\text{I}(\nu_e, e^-)^{127}\text{Xe}$	Accelerator DAR $\nu$	33%

As seen here, DAR  $\nu$  plays important role obviously.

For the SN physics, **good** measurements of “**various  $\nu$ -A interactions**” are crucial.

-> There have been measurements for various  $\nu$ -A cross-section

-> **still uncertainties are large**

# J-PARC neutrino experiments using Decay-At-Rest Neutrinos

- Generally, facilities for neutron spallation source also give the good DAR neutrinos.
- J-PARC Material and Life science Facility (MLF, Japan) is one of the best facility to get such neutrinos.
- Sterile Neutrino Search (JSNS<sup>2</sup>, JSNS<sup>2</sup>-II)
- Pb-ν cross section measurement (one test experiment)
- Some coherent scattering measurements.. (under proposals)

Collaboration meeting @ J-PARC (2024/ Feb)

JSNS<sup>2</sup> / JSNS<sup>2</sup>-II  
collaboration (58 collaborators)

- 7 Japanese institutions (25 members)
- 9 Korean institutions (24 members)
- 1 UK institution (1 member)
- 3 US institutions (5 members)
- 1 Chinese institution (3 members)

0.95 MW operation at MLF  
(1.0 MW at RCS)  
in 2024 April-May !

# JSNS<sup>2</sup> and JSNS<sup>2</sup>-II : Neutrino experiments using DAR

(JSNS2-I, JSNS2-II near detector  
17 t GdLS fiducial  
(4.6 m diameter x  
4.0 m height, 120 10" PMTs)

3GeV short pulsed beam

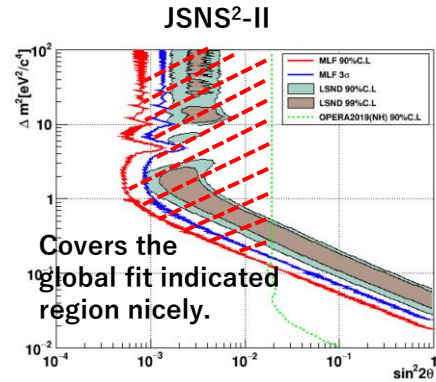

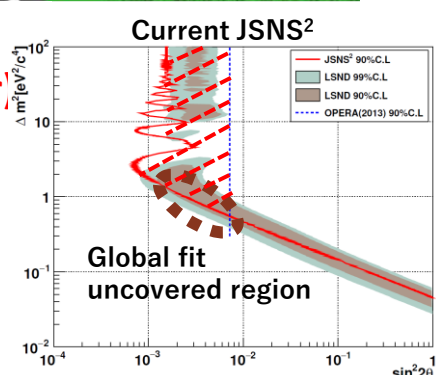

Searching for neutrino oscillation :  $\bar{\nu}_\mu \rightarrow \bar{\nu}_e$  with baseline of 24 m (near), and 48 m (far detector)

- (JSNS<sup>2</sup>): 1 MW x 3 y (near only)
- Commissioning (2020) and four long term physics runs (2023-2024)
  - Continue the physics runs
  - Analyses are on-going.

- (JSNS<sup>2</sup>-II): 1 MW x 5 y
- Proposed in 2020
    - New far detector: fiducial 32 tonnes and 48 m location.
    - Good sensitivity on low  $\Delta m^2$  region.
    - Two detectors with two different baselines -> a solid conclusion on LSND anomaly.
  - J-PARC/KEK granted the stage-2 approval in 2022.
  - Construction is almost completed. (now LS was already filled in this summer.)
  - Data taking coming soon!

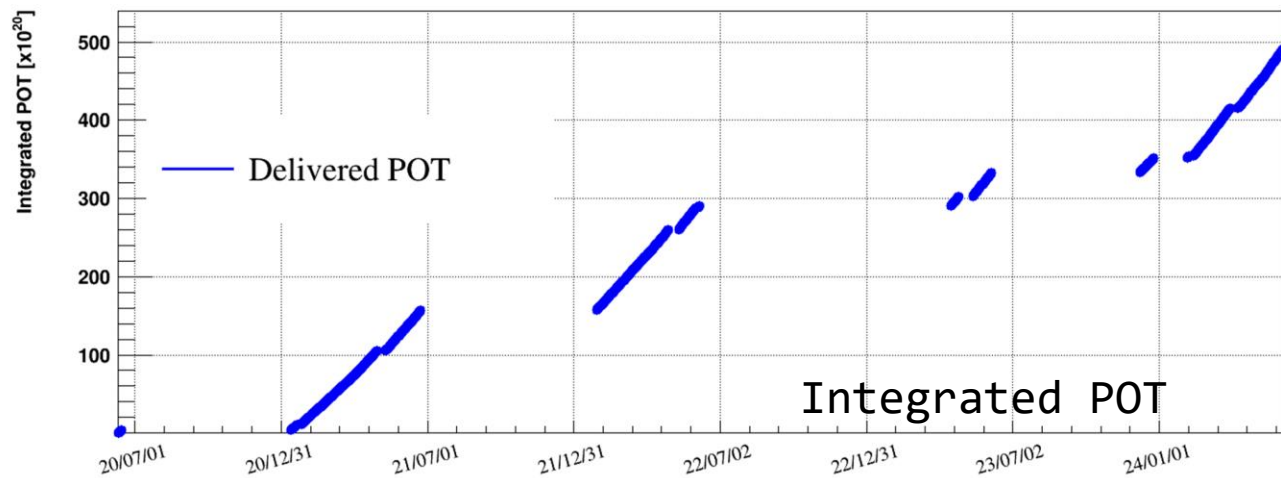

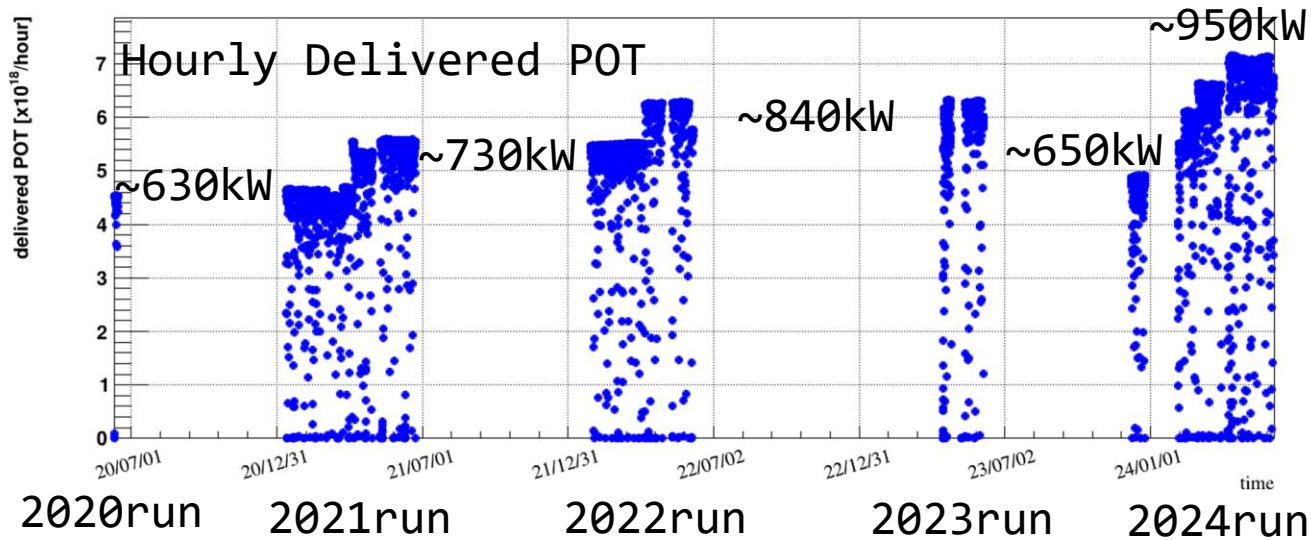

(JSNS<sup>2</sup>-II:  
Far detector  
32 t GdLS  
(6.2 m dia x  
6.2 m (h)  
228 10"  
PMTs)

# Beam power and Proton-On-Target (POT) (2020~2024) for JSNS<sup>2</sup>

## □ Beam power

- Achieved the designed values. (1.0MW @ RCS)
- Also 0.95 MW at MLF during 2024 April - May.

## □ POT

- Total  $4.85 \times 10^{22}$  POT has been accumulated
- 42.5% of approved POT for JSNS<sup>2</sup> (with single detector)

# Motivation to measure $^{12}\text{C}(\nu_e, e^-)^{12}\text{N}_{\text{g.s.}}$ (CNgs) reaction

- The number of  $\mu^+$  can be estimated by CNgs.

- parent particle:  $\mu^+ \rightarrow e^+ + \boxed{\nu_e} + \boxed{\bar{\nu}_\mu}$

CNgs    Sterile search

- No  $\pi/K$  production measurements on Hg+3GeV proton so far  $\rightarrow$  in-situ measurement

- CNgs:  $^{12}\text{C}(\nu_e, e^-)^{12}\text{N}_{\text{g.s.}}$

$^{12}\text{C} + \boxed{\nu_e} \rightarrow \boxed{e^-} + ^{12}\text{N}_{\text{g.s.}} \Rightarrow ^{12}\text{N}_{\text{g.s.}} \rightarrow ^{12}\text{C} + \nu_e + \boxed{e^+}$  lifetime:  $\sim 16$  ms,  $E_{\text{max}}=16.8\text{MeV}$

- prompt: electron, delayed: positron

- reaction of  $\nu_e$  (neutrino)

\* CNgs is useful to understand neutrino flux

- If production rates of  $\pi$  are measured externally, we can also measure the cross section of this reaction

- From energy spectra, we could search for neutrino oscillations from CNgs

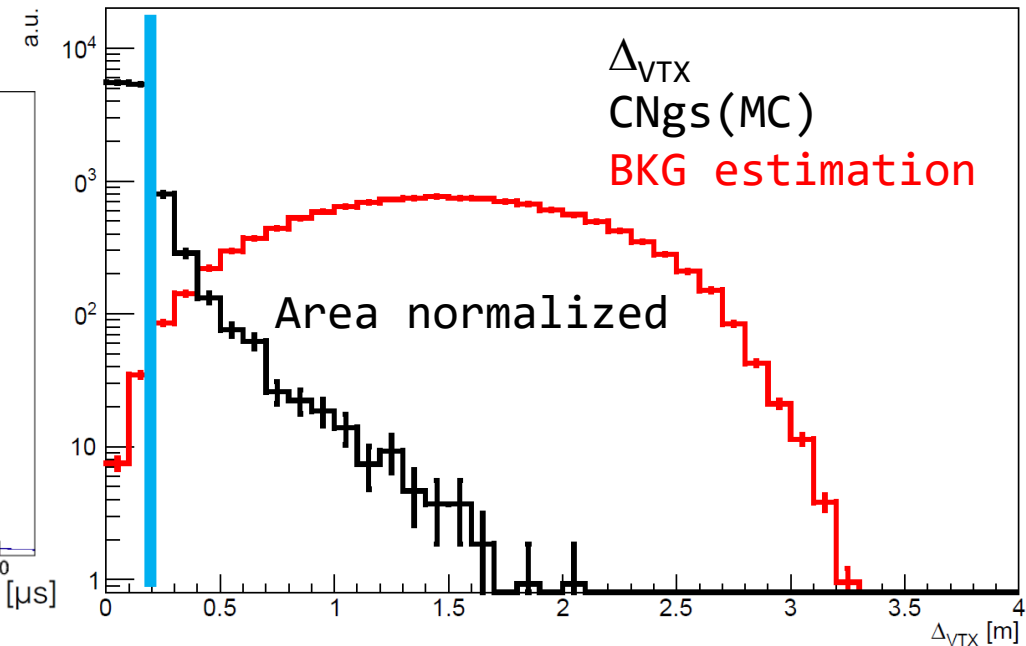

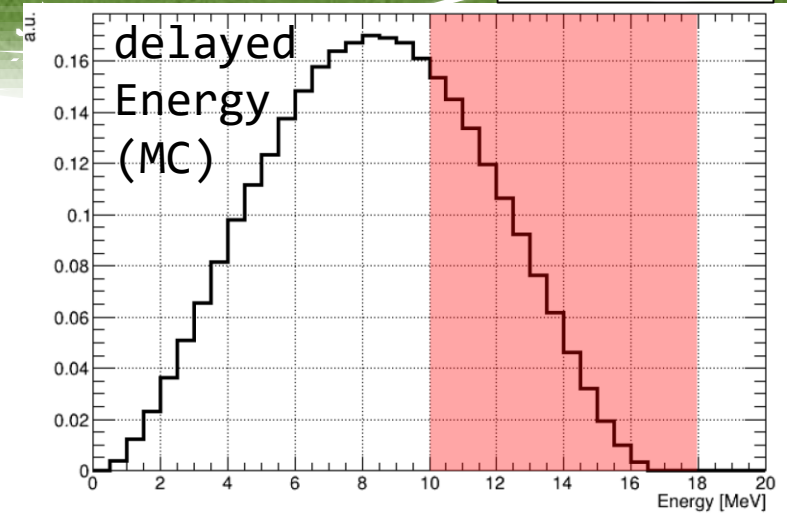

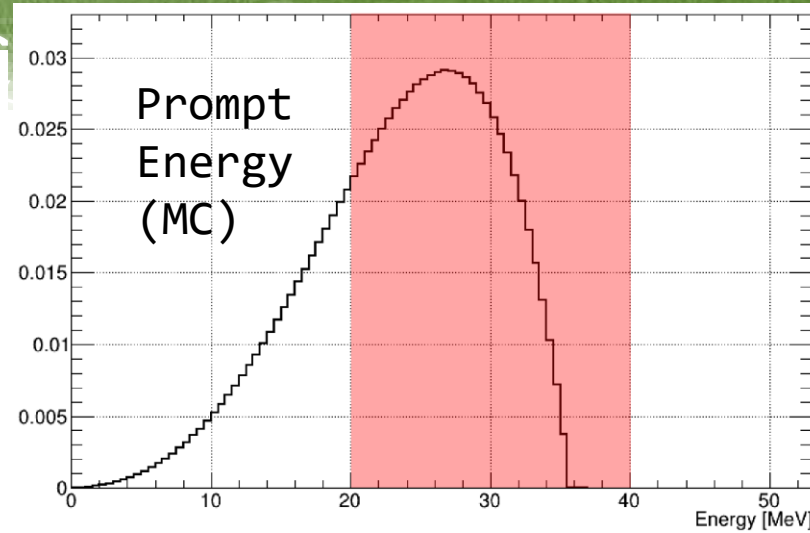

# Selection criteria for CNGs

$$P_e E_e (E_{\text{max.}} - E_e)^2 \frac{2\pi\eta}{e^{2\pi\eta} - 1}$$

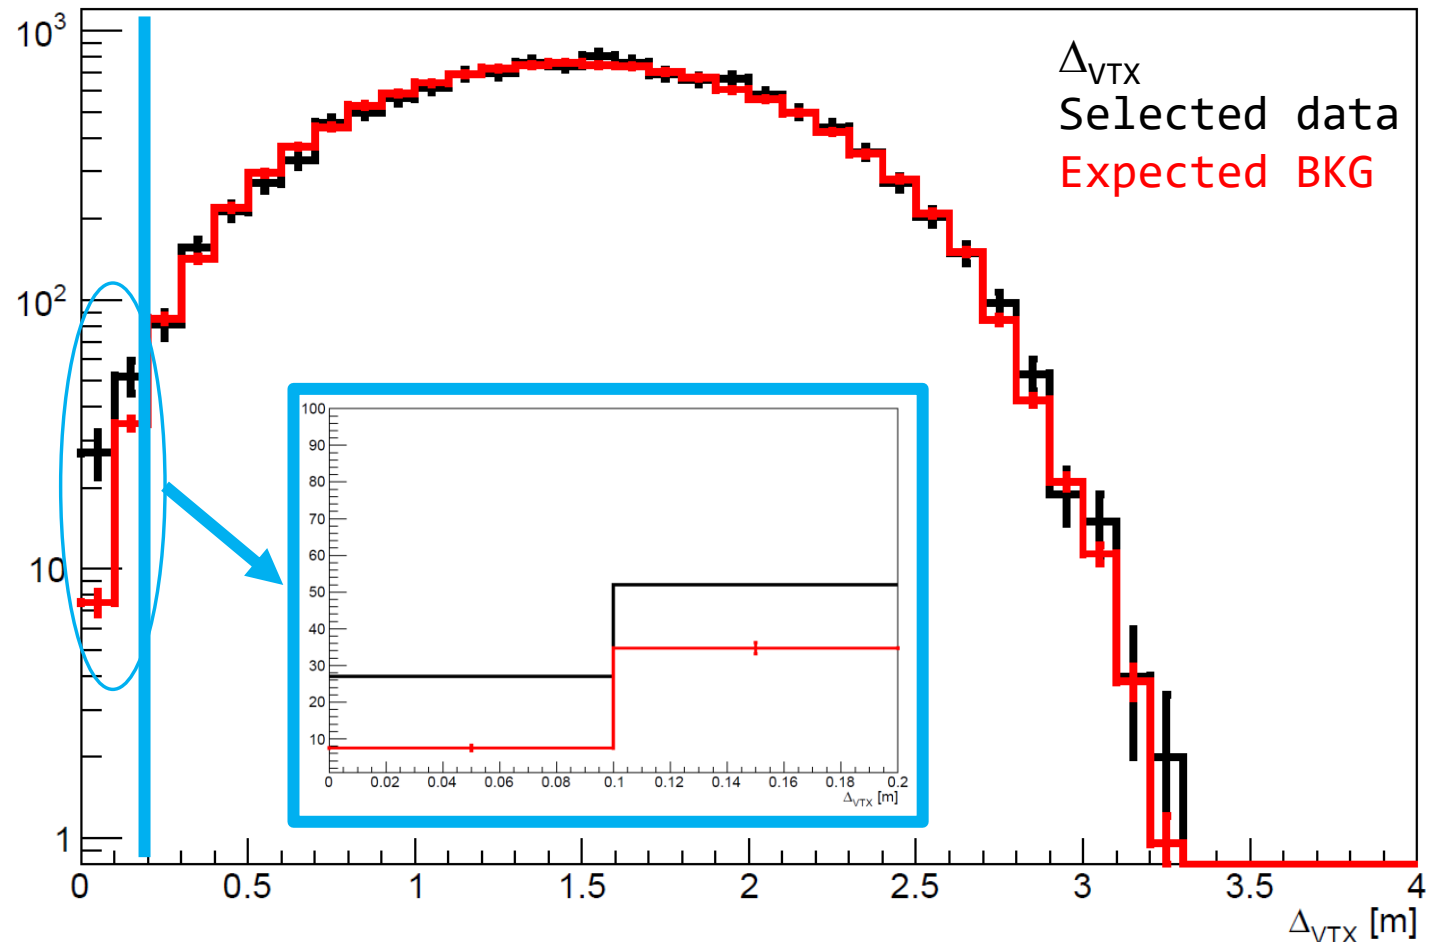

$$\eta = \frac{Z\alpha}{\beta_e}$$

- Energy
  - Prompt:  $20 < E < 40$  MeV
  - Delayed:  $10 < E < 18$  MeV
- Timing
  - Prompt:  $2 < T_{\text{beam}} < 10 \mu\text{s}$
- Prompt vs delayed
  - Spatial correlation:  $\Delta_{\text{VTX}} < 20 \text{cm}$  (most crucial cut)
  - Timing:  $0.2 < \Delta T < 12, 25 \text{ms}$   
(12ms : 2021  
25ms : 2022  
determined by trigger capability)
- Muon / Michel e veto
- Fiducial cut :  $|Z| < 100$  &&  $R < 140 \text{cm}$

# CNGs : selected data

- 2021-2022 data
  - $2.20 \times 10^{22}$  POT
- Clear excess is seen in signal region.
  - 79 events are observed.
  - $42.2 \pm 4.8$  (BKG, including syst.)
  - p-value:  $2.9 \times 10^{-7}$
  - More than 6 sigmas

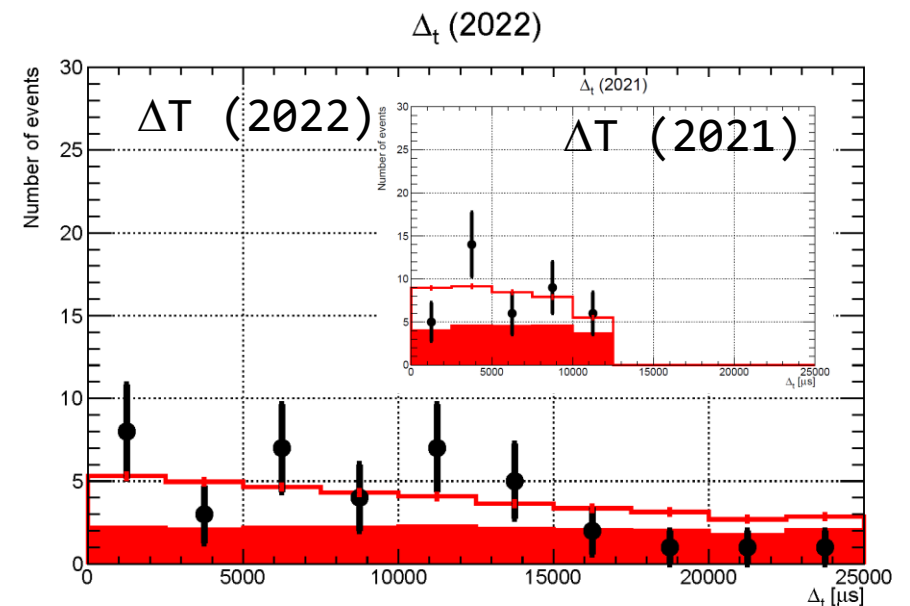

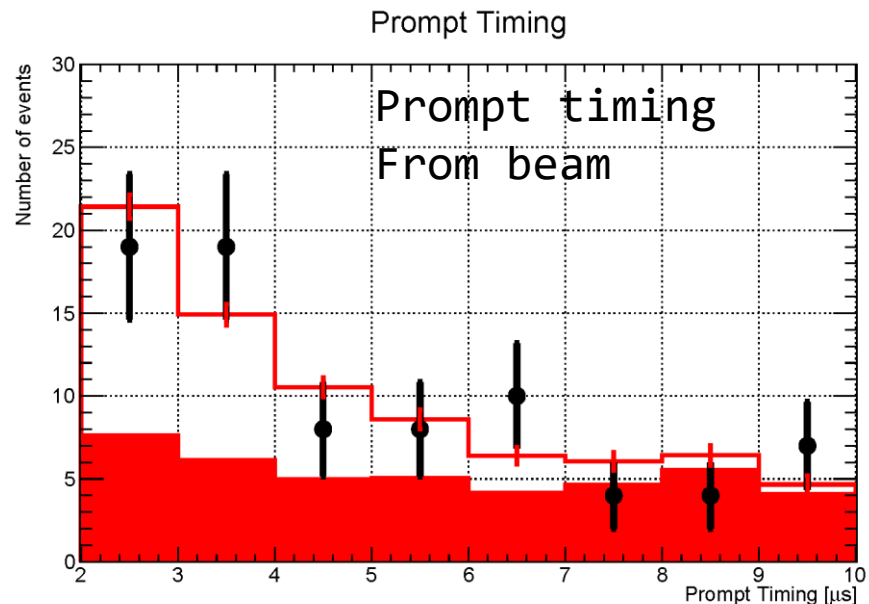

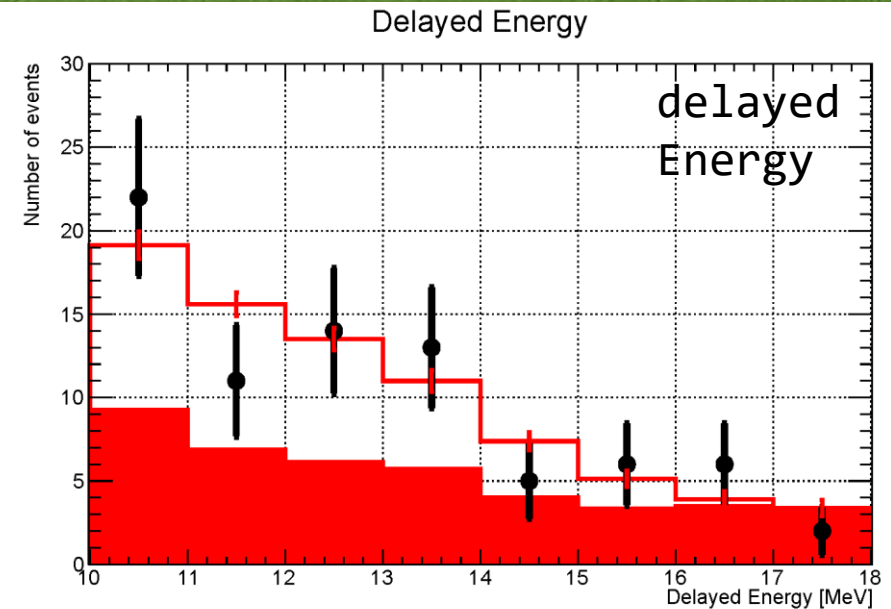

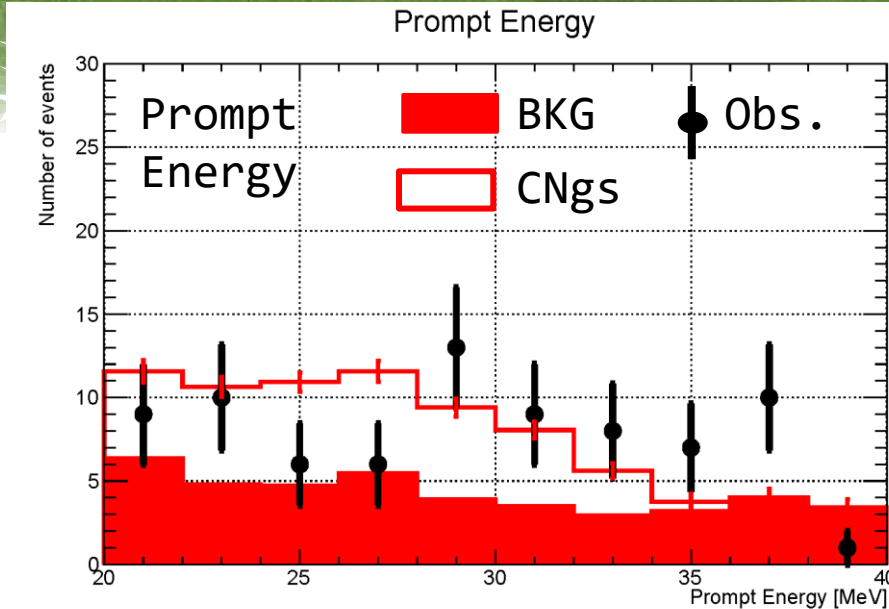

# Variables

□ All distributions for selected variables seem to be reasonable.

□  $36.8 \pm 10.2$  CNGs events

□  $(42.2 \pm 4.8)$  events for background).

□ Successfully observed  $O(10\text{MeV})$  neutrinos!!

# Interpretation to neutrino flux

- Cross section:  $\sigma$ 
  - Averaged cross sections from KARMEN / LSND is used.
  - $(9.1 \pm 0.7) \times 10^{-42} \text{ cm}^2$
- Number of  $^{12}\text{C}$  :  $N_{\text{target}}$ 
  - 10.7 tonnes of GdLS+DIN in fiducial
  - DIN concentration is 10% (vol.)
  - $(4.68 \pm 0.37) \times 10^{29}$
  - Error is dominated by fiducial volume determination. (arXiv:2404.04153)
- Efficiency :  $\varepsilon$ 
  - Averaged  $\varepsilon$  in 2021 and 2022 is  $5.88 \pm 0.21\%$
- $(1.47 \pm 0.36(\text{stat}) \pm 0.26(\text{syst})) \times 10^{14} / \text{cm}^2$  (obs) vs  $1.05 \times 10^{14}$  (FLUKA),  $0.82 \times 10^{14}$  (QGSP-BERT)
- Stat error is dominated. (~24%)
- Dominant systematic error is ~11% from methodology to estimate Nbkg.

$$N_{\text{eve}} = \text{Flux} \times \sigma \times N_{\text{target}} \times \varepsilon$$

$$\text{Flux} = N_{\text{eve}} / (\sigma \times N_{\text{target}} \times \varepsilon)$$

# Interpretation to pions/proton and plan

- $(0.48 \pm 0.14) \mu^+ / \text{proton}$  from this measurement.
  - Much higher production rates compared to ISIS / LAMPF due to proton energy and target.
  - ISIS (KARMEN) :  $0.0448 \pm 0.0030 \pi^+ / \text{proton}$
  - LAMPF (Los Alamos) :  $0.084 - 0.090 \mu^+ / \text{proton}$
  
- Once the production rate measurements of  $\pi^+$  production (between 3 GeV p and Hg) was done, a precise cross section measurement of CNGs can be done.
  - We have more than 10 times POT in JSNS<sup>2</sup> and JSNS<sup>2</sup>-II.
    - 2 times data compared to this results in our hand already.
    - Additional POTs (6.7 times of current one) are approved by KEK/J-PARC.
  
- (Maybe we can also feed back to the electron neutrino disappearance oscillation)

# JSNS2 can be nu-A factories?

*Just private consideration now*

A nu-A interaction also can be measured by putting **material block** at the center of the detector.

**JSNS<sup>2</sup> can be v-A measurement factory ?**

# Cross section measurements using Mono-energetic neutrinos ( $\sim 236$ MeV)

- 3 GeV (of proton) is very close to open the production channels of Kaons. (MLF provides a unique opportunity)

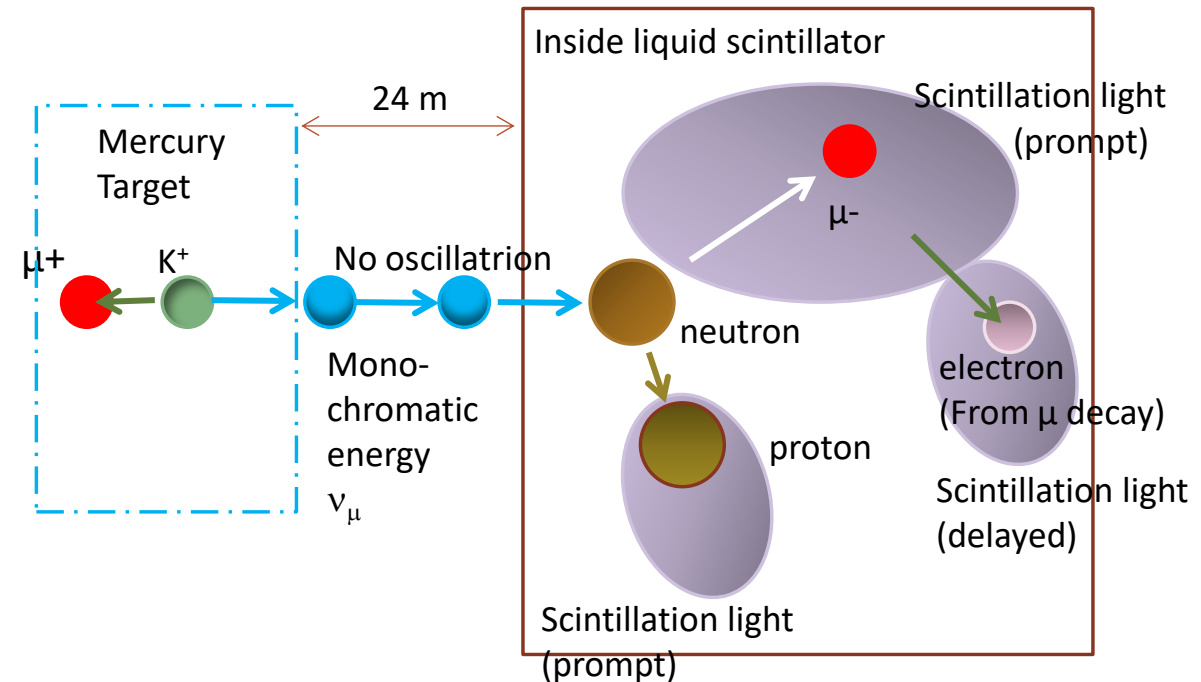

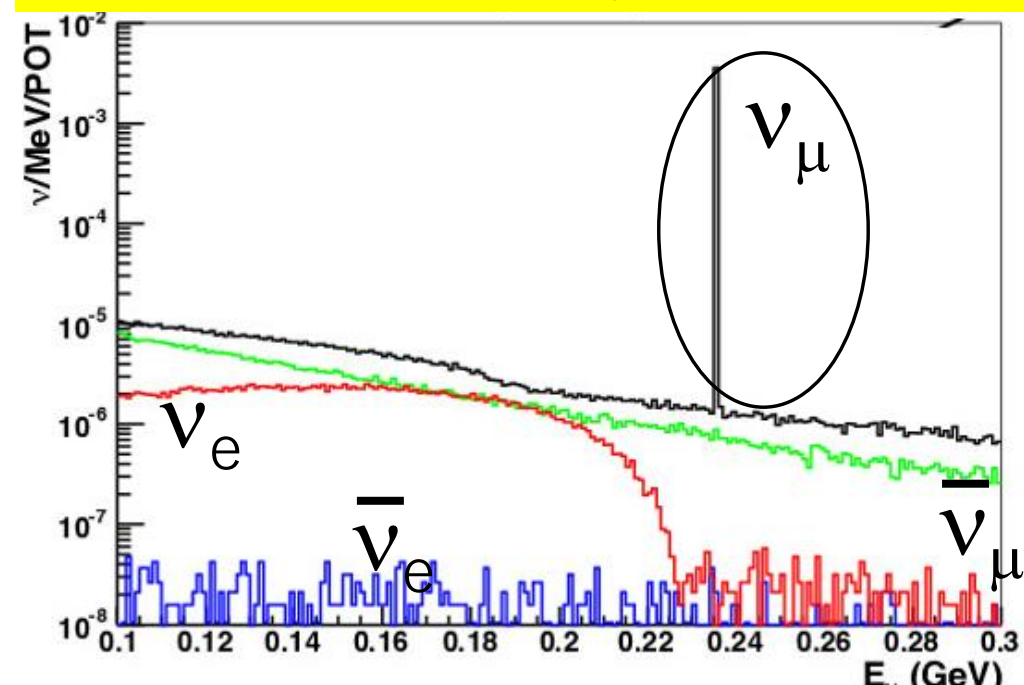

arXiv:2409.01383  
(also submitted to PRL)

# KDAR (Kaon Decay-At-Rest) $\nu$

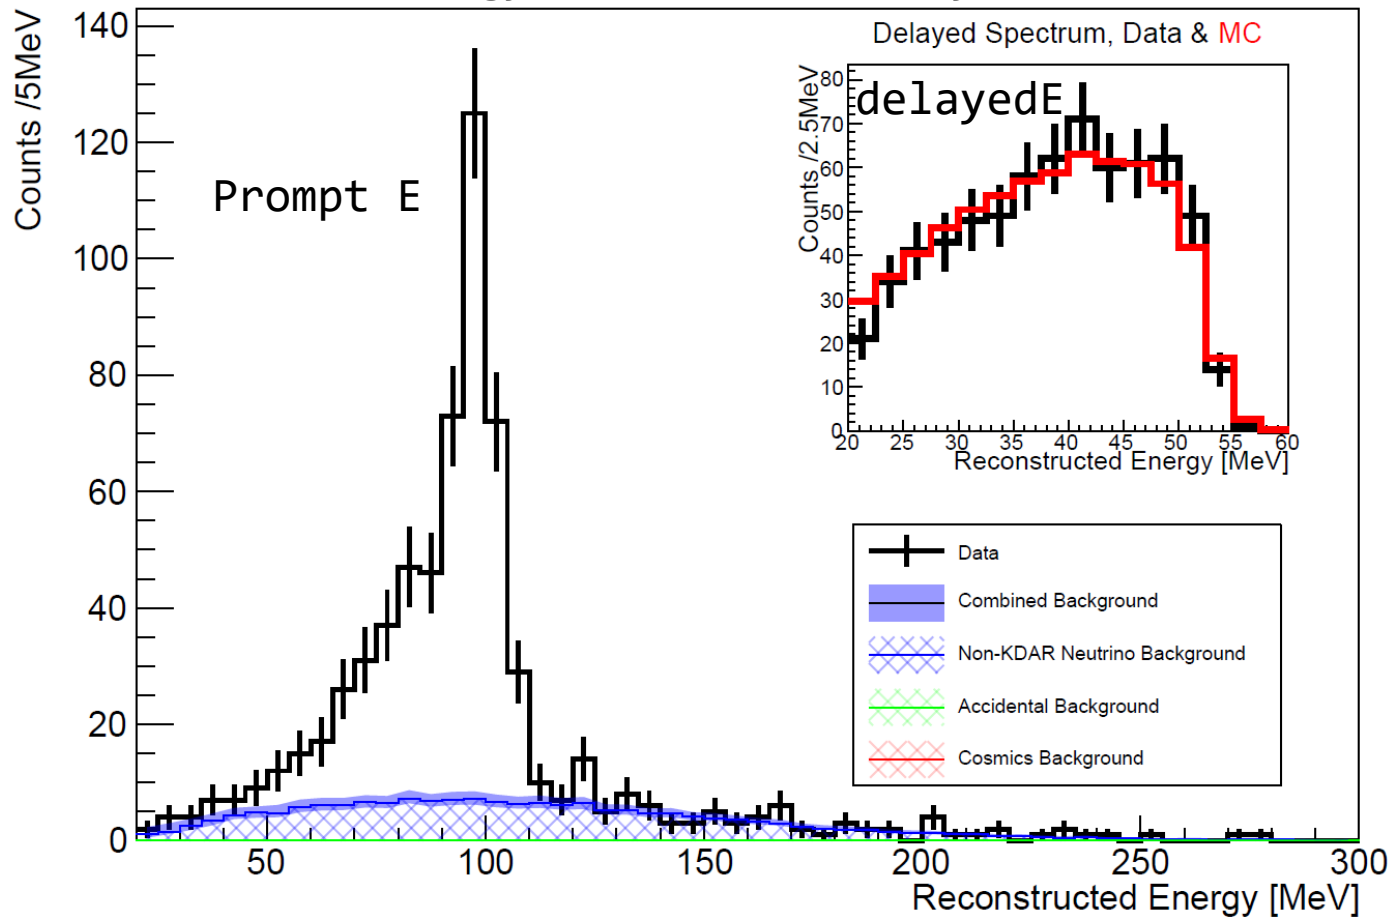

- Mono-energetic muon neutrinos from  $K\mu 2$  (decay-at-rest) gives a rare opportunity to investigate the quasi-elastic interactions and their regarding effects from nucleus. (e.g.: Fermi gas model, FSI, etc..)
- In neutrino experiment, the horn focused beam provides wide neutrino energy.

$\nu$  energy from  $K^+$  DAR ( $K\mu 2$ ): monochromatic

# Selection / background

observed energy : 2021 data only  $1.4 \times 10^{22}$  POT

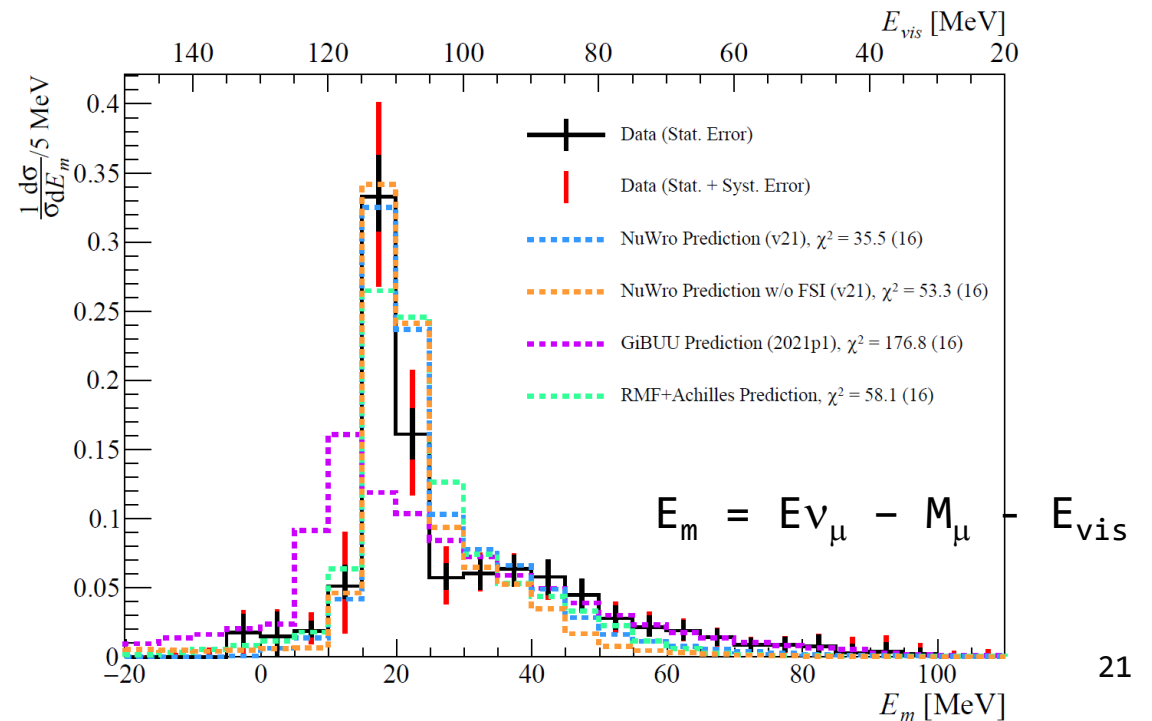

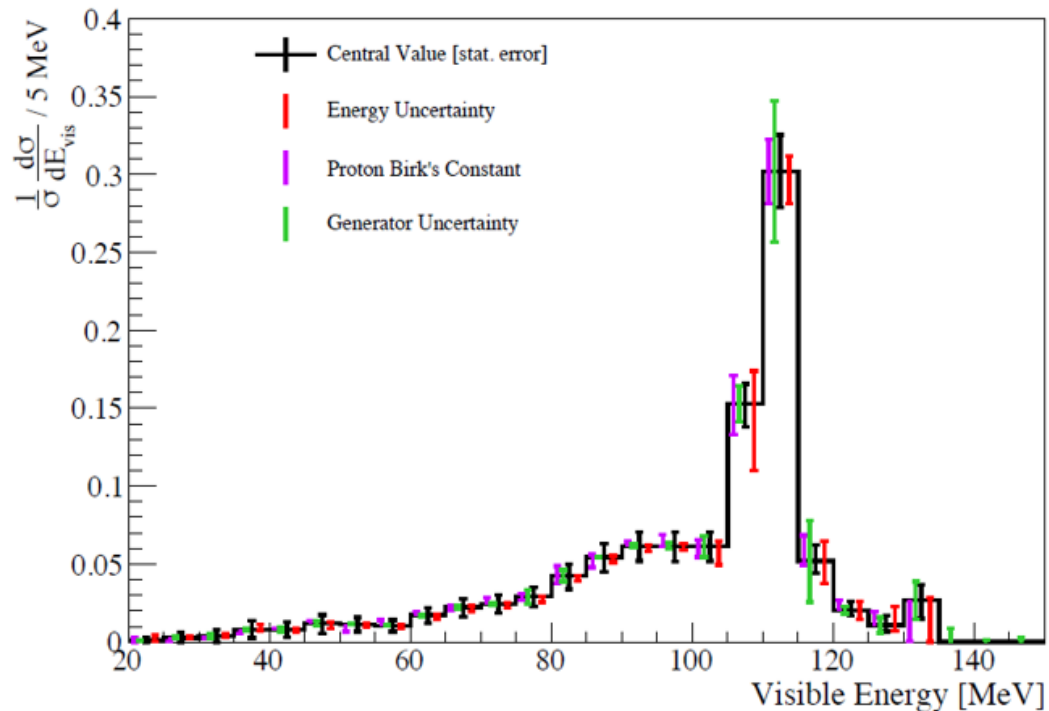

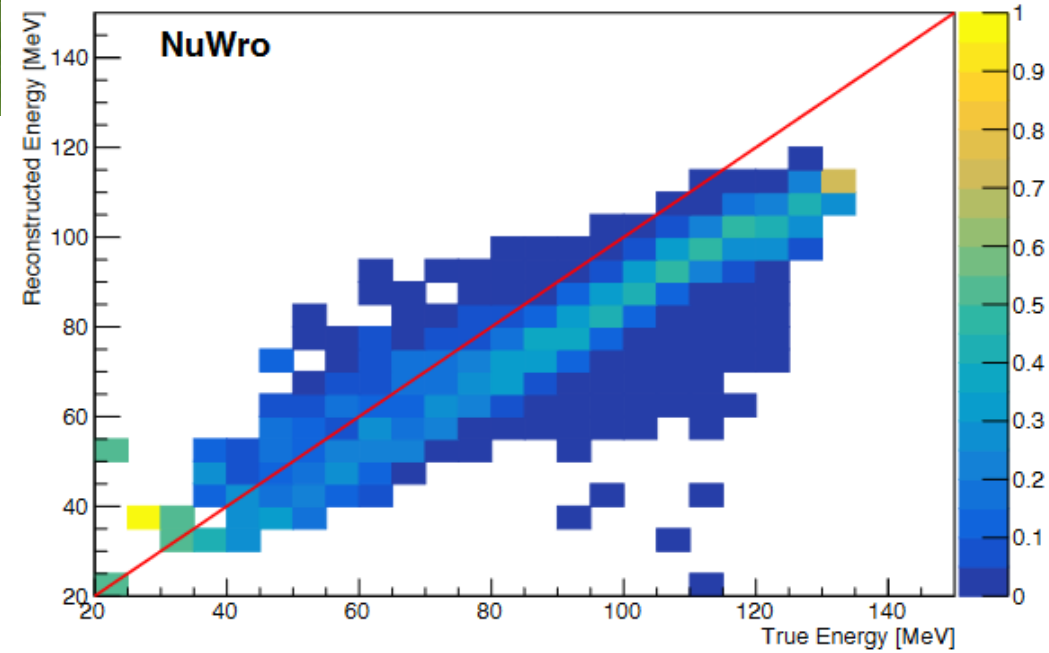

621 selected events  
(144 $\pm$ 21 is BKG.)  
(20-150MeV)

	Prompt	Delayed
<b>Energy</b>	20-150 MeV	20-60 MeV
<b>Timing</b>	2x150ns Beam centered windows	$\Delta t < 10\mu s$
<b>Position</b>	Fiducial Volume: R<1400mm -1000mm < z < 500mm	$\Delta \text{Vertex} < 300\text{mm}$

# KDAR results

- Energy unfolding (removal of detector effects) was done by MC. (true E vs observed E matrix)
  - Iterative Bayes (D'Agostini) method was used.
  - Matrix on True Evis vs reconstructed energy was made by KDAR MC (top-right).
  - Shape only measurement. (K production rate is unknown in Hg-p (3GeV).
- The largest systematic uncertainty is coming from generator dependence.
  - Balance of muon / proton energy gives large difference. (proton gives different response from MIP like particles)

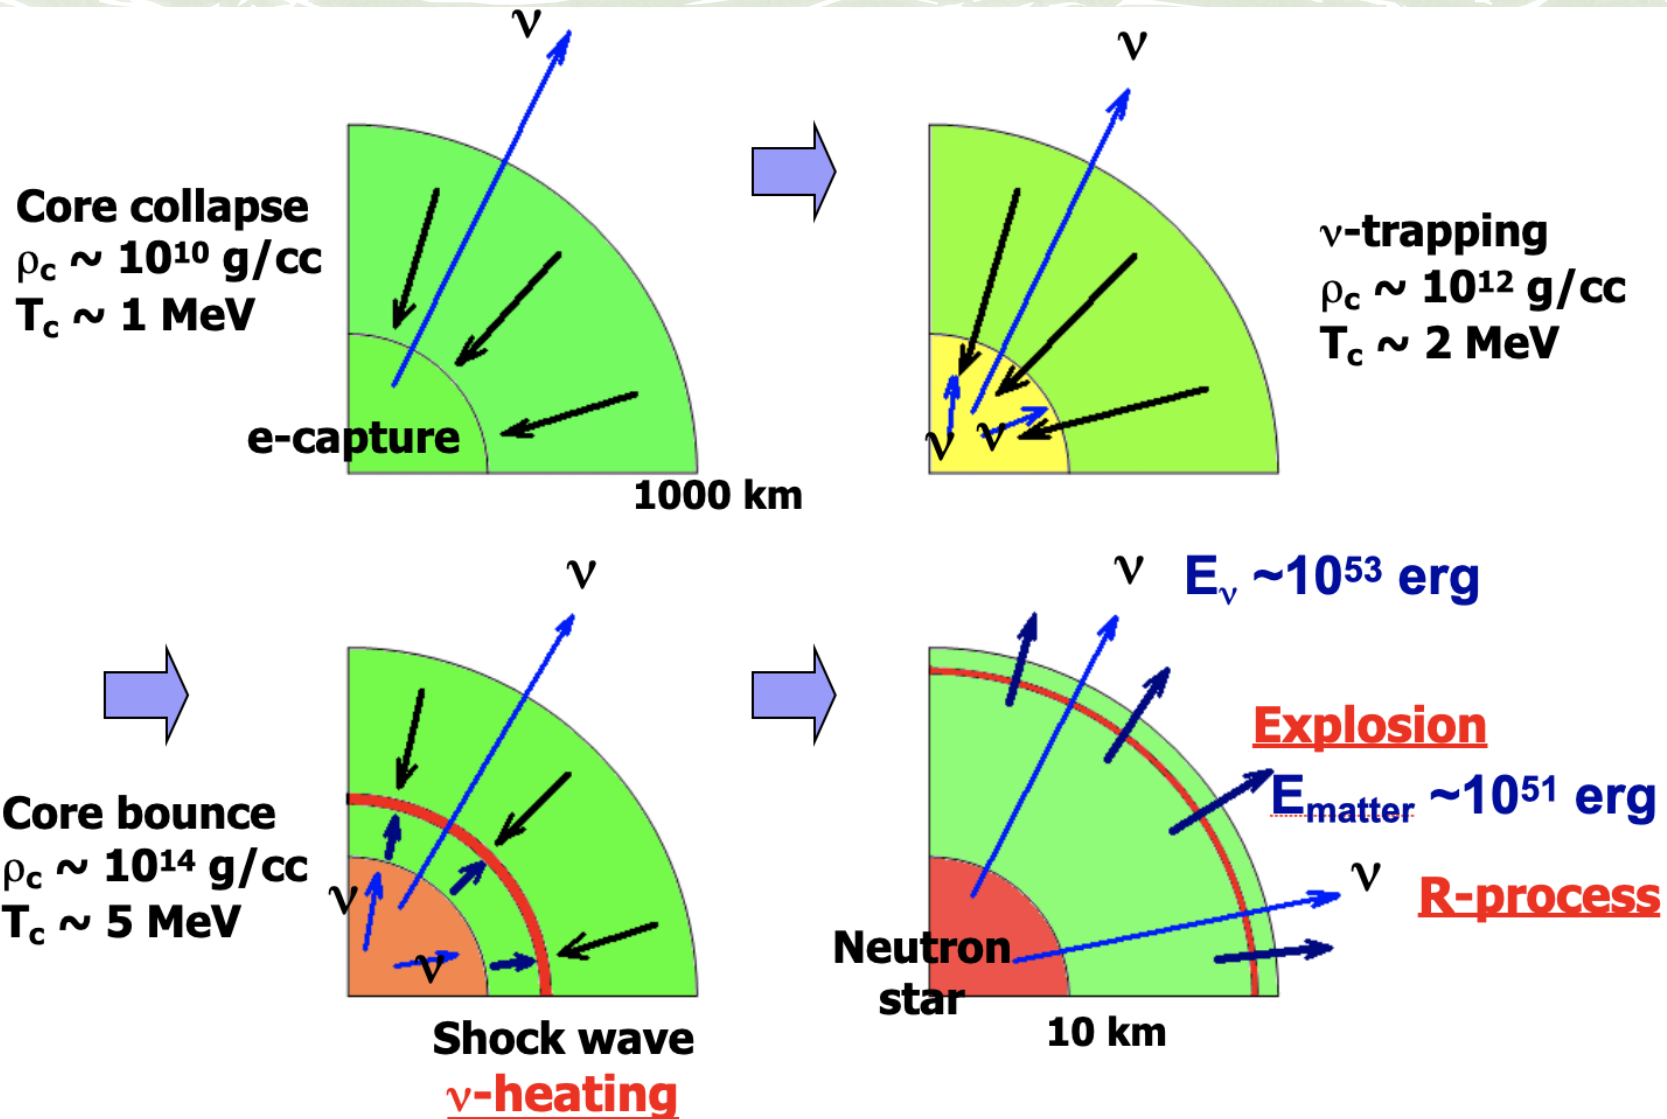

# Summary

- ❑ Decay-At-Rest neutrinos are useful tool for various physics.
  - ❑ Cross section measurements of neutrinos with  $O(10 \text{ MeV})$  and  $O(100 \text{ MeV})$  energies.
  - ❑ Search for neutrino oscillation with short baseline
- ❑ Facilities for the neutron spallation source is potentially good DAR  $\nu$  sources at the same time.
  - ❑ ISIS (UK), SNS (US, ORNL), MLF (Japan, J-PARC), CSNS (China), ESS (Europe), ...
- ❑ JSNS<sup>2</sup> (J-PARC Sterile Neutrino Search at J-PARC Spallation Neutron Source) just began to observe the neutrinos produced by DAR.
- ❑ We are taking data. Also a new 48m detector have been built recently. Exciting time continued !!

# backup

# Core collapse of Supernova

# MLF mercury target and Intrinsic $\bar{\nu}_e$ BKG estimation

	Target	$\pi^-$ absorb	$\mu^-$ capture	suppression	$\times \pi^-/\pi^+$
LSND	H2O	96%	88%	$5 \times 10^{-3}$	$\times 0.13$
J-PARC	Hg(+Fe+Be)	99%	$\sim 80\%$	$1.7 \times 10^{-3}$	$\times 1.$

# Prompt energy

- Prompt energy for CNgs is determined by energy of  $\nu_e$  from  $\mu^+$  and cross section.

energy of  $\nu_e$  from  $\mu^+$

cross section

energy of  $\nu_e$  with cross section

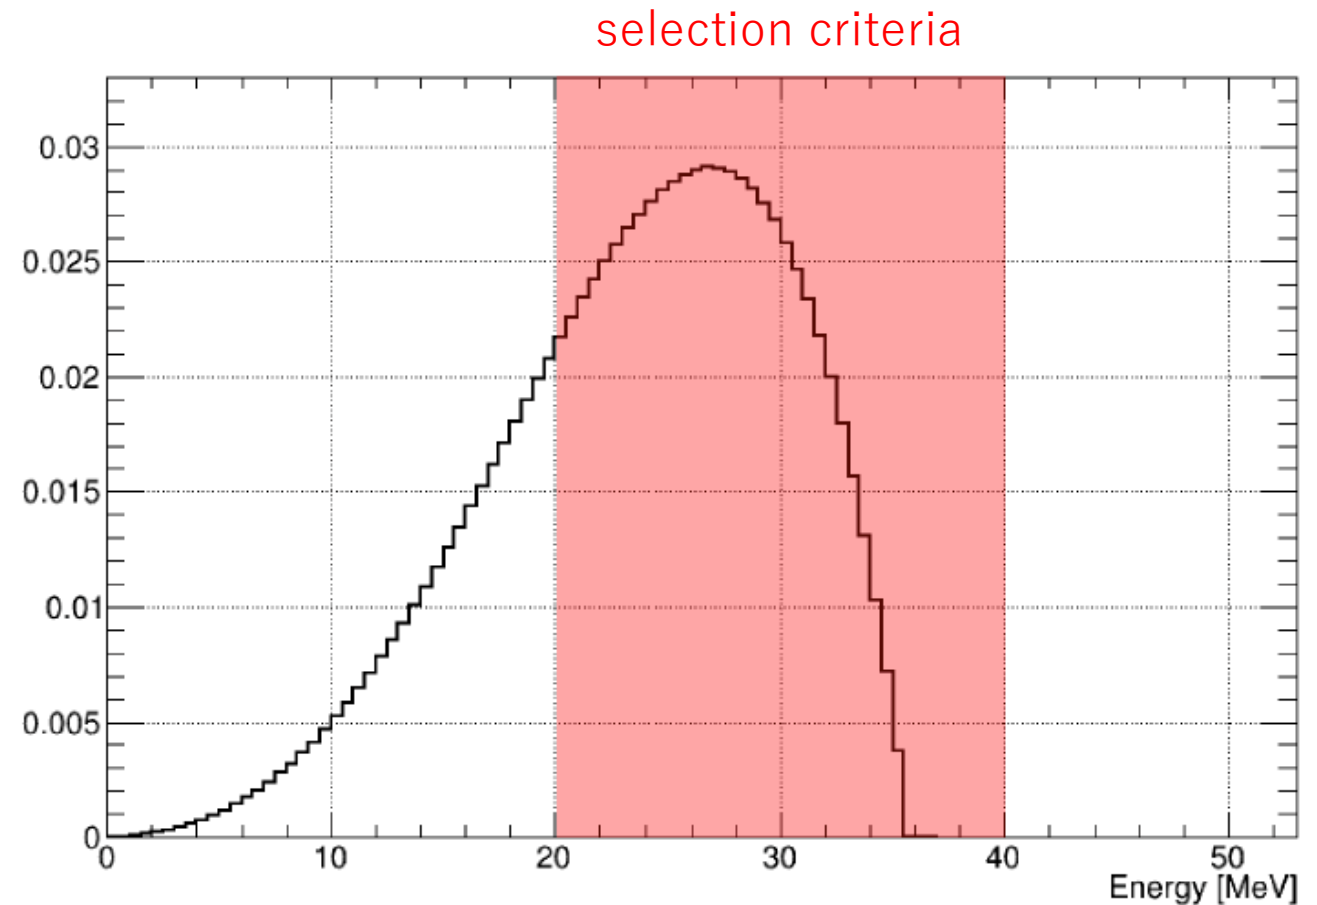

M. Fukugita, Y. Kohyama, and K. Kubodera, "Neutrino Reaction Cross Sections on  $^{12}\text{C}$  Target", Phys. Lett. B 212 (1988) 139–144

# Prompt energy

- Q-value of the  $\nu_e$ - $^{12}\text{C}$  reaction is 17.3 MeV.
- Right plot shows the prompt energy from the theoretical formula.

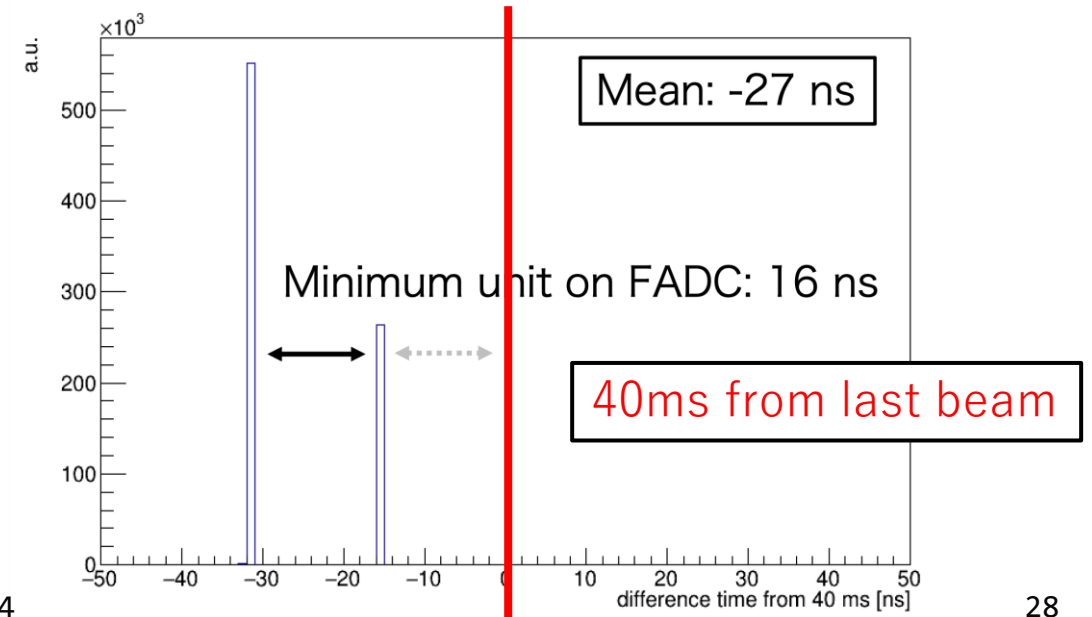

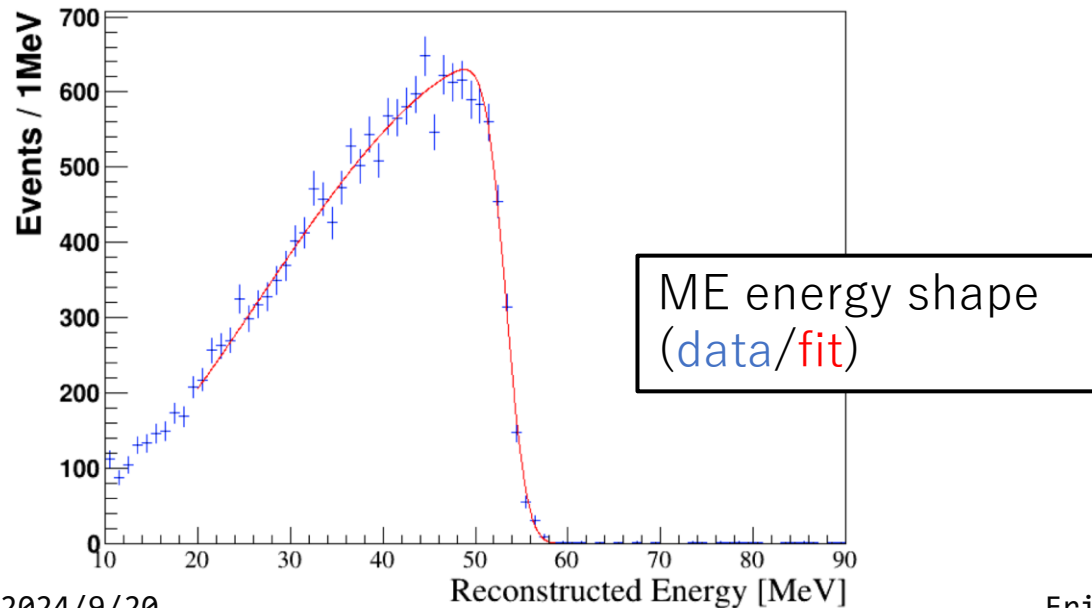

-17.3 MeV

# Precise energy and timing calibrations

- We can use n-Gd captured events ( $\sim 8$  MeV) and Michel electrons from  $\mu$  ( $\sim 53$  MeV)
  - Careful energy calibration can be done for CNGs prompt (20-40 MeV) and delayed (10-18 MeV) events.
- The sources of the systematic uncertainties
  - Time variation, spatial dependence, quenching factor of LS (mainly)
  - Scale error is less than 1%.
- Timing of FADC was calibrated by accelerator RF timing. (every 40ms).  $\rightarrow$  negligible error.
