Jens Langelage

Thermal lattice QCD	Deconfinement transition	Cold, dense matter	Outlook
Outline			

- Define effective theory by integrating out spatial degrees of freedom
- Effective theory can be simulated very fast by different algorithms
- No solution to the sign problem, but a huge reduction of its severity
- Disadvantage: Expansion starts from the unphysical strong coupling and infinite quark mass region

(日) (同) (三) (三)

ETH Zürich

Starting point: QCD with Wilson's Action

Partition function

$$Z = \int [dU_0][dU_k] \exp\left[\frac{\beta}{3} \sum_p \operatorname{Re} \operatorname{Tr} U_p\right] \qquad \beta = \frac{6}{g^2}$$

Plaquettes consist of 4 links: $U_{\mu}(x) = \exp\left[iagA_{\mu}(x)\right]$

• Expansion in $\beta \doteq$ Strong coupling expansion

Jens Langelage

< ロ > < 同 > < 回 > < 回

ETH Zürich

Starting point: QCD with Wilson's Action

 Quark part after Grassmann integration (per flavor and omitting spin and color indices):

$$e^{S_q} = \det \left[\delta_{xy} - \kappa \sum_{\pm \nu} (1 + \gamma_{\nu}) U_{\nu}(x) \, \delta_{x,y-\hat{\nu}} \right] \qquad \kappa = \frac{1}{8 + 2am}$$

Expansion in $\kappa \doteq$ Hopping parameter expansion

 \rightarrow Everything is expressed in link variables \in SU(3)

Physical observables are functions of (β, κ). Here we expand around (β = 0, κ = 0), i.e. infinite coupling and quark mass

• • • • • • • • • • • • •

FTH Zürich

- Graphical expansion: Build graphs of plaquette and link variables
- \blacksquare Plaquettes contribute a factor of β
- Quark hops contribute a factor of κ
- Integrate over all link variables

Thermal lattice QCD

Finite temperature:

- Compactified time direction
- Periodic boundary conditions for bosons
- Antiperiodic boundary conditions for fermions
- Order parameter: Polyakov loop

$$\operatorname{Tr} W(\vec{x}_i) = \operatorname{Tr} \prod_{\tau=1}^{N_{\tau}} U_0(\tau, \vec{x}_i) = L(\vec{x}_i) = L_i$$

Finite chemical potential:

Modified temporal hopping parameter

$$\kappa \rightarrow \kappa e^{a\mu}$$
 positive direction
 $\kappa \rightarrow \kappa e^{-a\mu}$ negative direction

3 →

ETH Zürich

Integrating out spatial link variables: Defines effective action

$$Z=\int [dU_0][dU_k]e^{\mathcal{S}_{
m g}+\mathcal{S}_q}\equiv\int [dU_0]e^{\mathcal{S}_{
m eff}}$$

Advantages:

- S_{eff} depends only on Polyakov loops; (3+1)d theory can be reduced to effective 3d theory
- Complex numbers instead of group elements
- Disadvantages:
 - Infinite number of effective interaction terms and couplings
 - Couplings only known to some order from strong coupling and hopping parameter expansion

<ロ> <回> <回> <三> <三> <三>

FTH Zürich

< ロ > < 同 > < 三 > < 三

FTH Zürich

Leading order effective theory

Quark part

- Neglect spatial plaquettes and spatial quark hops
 The spatial integrations can be calculated exactly
 The spatial plaquet has no spatial link dependence at all
- The quark part has no spatial link dependence at all

$$e^{S_q} = \prod_i \det \left[1 + h_1 W_i\right]^2 \left[1 + \overline{h}_1 W_i^{\dagger}\right]^2$$

Effective coupling: h₁(κ, μ) = (2κe^μ)^{N_τ} = h
₁(κ, -μ)
 Further simplification (in case of SU(3)):

$$\det\left[1+h_1W\right] = 1+h_1L+h_1^2L^*+h_1^3$$

Jens Langelage

• • • • • • • •

Leading order effective theory

Gauge part

• Chain of N_{τ} plaquettes in the same representation

Nearest neighbor Polyakov Loop interaction

Jens Langelage Thermal lattice QCD as a spin model ETH Zürich

(日) (同) (三) (三)

Leading order effective theory: Remarks

$$Z = \int [dW] \prod_{i} \det \left[1 + h_1 W_i \right]^2 \left[1 + \overline{h}_1 W_i^{\dagger} \right]^2 \prod_{\langle ij \rangle} \left[1 + 2\lambda_1 \operatorname{Re} L_i L_j^* \right]$$

- \blacksquare Simulation yields critical h_1^c and $\lambda_1^c \quad \to \quad \beta^c$ and κ^c
- Can be done for each N_{τ} , need h_1^c and λ_1^c only once
- The well-known SU(3) spin model is the first order approximation to this
- Spatial plaquettes and quark hops contribute higher orders to the leading couplings and introduce new interaction terms

Solving the effective theory: Pure gauge theory

• Solve effective partition function for λ_1^c

$$Z = \int [dL] e^{V(L)} \prod_{\langle ij \rangle} \left[1 + \lambda_1 \left(L_i L_j^* + L_i^* L_j \right) \right]$$

• We get $\lambda_1^c = 0.18805(2)$

• Use this value to convert to $\beta_c(N_{\tau})$

$$\lambda_1(\beta, N_{\tau}) = \left(\frac{\beta}{2N_c^2}\right)^{N_{\tau}} \exp\left[N_{\tau}\left(P(\beta)\right)\right]$$

Crucial point: Knowledge of λ₁ as a function of β and N_τ
 Polynomial P(β) known up to O(β¹²)

ETH Zürich

Deconfinement transition

Evolution of $\beta^{c}(N_{\tau})$ for different truncations and SU(2)

Jens Langelage

ETH Zürich

Fermionic corrections: Examples

• Corrections to the leading coupling: $\mathcal{O}(\kappa^{N_{\tau}+2}u)$

 \longrightarrow Deconfinement transition

• New interaction terms: $\mathcal{O}(\kappa^{2N_{\tau}+2})$

Jens Langelage

Deconfinement transition: $\mu = 0$

• Use the leading order effective theory and $\overline{h}_1 = h_1$

$$Z = \int [dW] \prod_{i} \det \left[1 + h_1 W_i \right]^2 \left[1 + h_1 W_i^{\dagger} \right]^2 \prod_{\langle ij \rangle} \left[1 + 2\lambda_1 \operatorname{Re} L_i L_j^* \right]$$

- With increasing h₁, the transition turns from first order to crossover at a second order endpoint
- Corrections of higher interaction terms negligible

Jens Langelage

• • • • • • • • • • • • • •

ETH Zürich

Deconfinement transition: $\mu = 0$

Comparison with other approaches

Comparison with 4d simulations

• Conversion to quark masses via $\kappa = \frac{1}{2}e^{-aM_q}$

N _f	M_c/T	$\kappa_c(N_{\tau}=4)$	$\kappa_{c}(4)$, Ref. [1]	$\kappa_{c}(4)$, Ref. [2]
1	7.22(5)	0.0822(11)	0.0783(4)	~ 0.08
2	7.91(5)	0.0691(9)	0.0658(3)	-
3	8.32(5)	0.0625(9)	0.0595(3)	-

Table : Location of the critical point for $\mu = 0$ and $N_{\tau} = 4$. Existing literature: [1] Saito et al. (2011), [2] Alexandrou et al. (1998)

Deconfinement transition: $\mu \neq 0$

$$Z = \int [dW] \prod_{i} \left[1 + h_1 L_i \right]^2 \left[1 + \overline{h}_1 L_i^* \right]^2 \prod_{\langle ij \rangle} \left[1 + 2\lambda_1 \operatorname{Re} L_i L_j^* \right]$$

- Metropolis algorithm: Mild sign problem
- Worm algorithm: No sign problem

Comparison of the two algorithms: Quark number density for $\frac{\mu}{T} = 1; 2$

Deconfinement transistion: $\mu \neq 0$

Critical $\frac{M}{T}$ for all chemical potentials

<ロ> <四> <四> <日> <日> <日</p>

ETH Zürich

Deconfinement transition: $\mu \neq 0$

3d columbia plot

Cold and dense matter

• $T \simeq 0$ is at finite *a* realized by large $N_{ au}$

$$\lambda_1(eta=5.7, N_{ au}=115) \sim 10^{-27}$$

- $\blacksquare \Rightarrow$ Effective gauge part can be neglected
- Not to be confused with strong coupling limit: λ_1 is small, not β
- Effective theory then reads:

$$Z = \int [dW] \prod_{i} \det \left[1 + h_1 W_i \right]^2 \left[1 + \overline{h}_1 W_i^{\dagger} \right]^2$$

No interactions, single-site problem: Can be solved analytically

Image: A math a math

Cold and dense matter

Interactions

Leading interaction term:

 This graph alone spoils baryon saturation at large densities: Need to resum all winding numbers

Jens Langelage

Cold and dense matter Results:

Transition to nuclear matter:

- Not yet clear, if this happens at T = 0 or T > 0 (as in nature)
- Binding energy exponentially suppressed with pion mass (~ 20GeV in our truncation)

Jens Langelage

- Measure effective couplings nonperturbatively
- Ansatz for full effective action after spatial link integration:

$$e^{S_{\text{eff}}} = \sum_{\{r_i\}} c\left(\{r_i\}\right) \prod_i \chi_{r_i}(W_i)$$
$$= c(\{0\}) \left[1 + \sum_{\{r_i\}} \lambda\left(\{r_i\}\right) \prod_i \chi_{r_i}(W_i)\right]$$

• Using character orthogonality λ_i are obtainable, e.g

$$c(\{0\}) = \int [dW] e^{S_{\text{eff}}} = \int [dW] [dU_i] e^S = Z$$

$$\lambda_1 = \frac{1}{Z} \int [dW] e^{S_{\text{eff}}} \chi_f(W_i) \chi_{\bar{f}}(W_j) = \langle L_i L_j^* \rangle$$

ETH Zürich

Jens Langelage

- Neglect higher order interaction terms
- Goal: Reduce remaining uncertainty for SU(3)

ETH Zürich

Jens Langelage

- Constructed effective theory with much milder sign problem
- In good agreement with full simulations, where comparison is possible (heavy quarks)
- Gauge part seems to be under control especially with nonperturbatively extracted effective couplings
- Fermionic sector more complicated (as always) due to the 4d simulations involved
- Main advantage: Dependence of the couplings on chemical potential is trivial, determination at $\mu = 0$ suffices
