

Lattice QCD under extreme conditions

I Equation of State

II Transition

Edwin Laermann

III Critical behavior ?!

for the
RBC-Bielefeld – and
hotQCD – Collaborations

I Equation of State

the equation of state is $\epsilon(p)$

equivalent to knowing pressure $p(T)$ and energy density $\epsilon(T)$

\Rightarrow entropy density $s = (\epsilon + p)/T$ and other quantities through thermodynamic relations

start from energy-momentum tensor $\frac{\Theta_\mu^\mu(T)}{T^4} = \frac{\epsilon - 3p}{T^4} = T \frac{d}{dT}(p/T^4)$

where $\frac{p}{T^4} = \frac{1}{VT^3} \ln Z(T, V) - \lim_{T \rightarrow 0} \frac{1}{VT^3} \ln Z(T, V)$ $T = 0$ subtraction takes care of UV divergencies

now $Z(T, V; g, m_l, m_s) = Z(N_\tau, N_\sigma, a; \beta = 6/g^2, \hat{m}_l, \hat{m}_s) \rightarrow Z(N_\tau, N_\sigma, a; \beta, m_\pi, m_K)$

and tune bare lattice parameters \hat{m}_l, \hat{m}_s with β such that $m_{\pi, K} = \text{const} \Rightarrow \hat{m}_{l,s}(\beta), a(\beta)$

$$\Rightarrow \quad \underline{\text{central quantity}} \quad \frac{\Theta_\mu^\mu(T)}{T^4} = -R_\beta(\beta) N_\tau^4 \left(\left\langle \frac{d\bar{S}}{d\beta} \right\rangle_T - \left\langle \frac{d\bar{S}}{d\beta} \right\rangle_{T=0} \right)$$

$$\text{with} \quad R_\beta(\beta) = T \frac{d\beta}{dT} = -a \frac{d\beta}{da} \quad \text{(non-perturbative) } \beta \text{ function}$$

$$\text{then} \quad \frac{p(T)}{T^4} - \frac{p(T_0)}{T_0^4} = \int_{T_0}^T dT' \frac{1}{T'^5} \Theta_\mu^\mu(T')$$

action $S = \beta S_G + 2\hat{m}_l(\beta) \bar{\psi}_l \psi_l + \hat{m}_s(\beta) \bar{\psi}_s \psi_s + \beta$ independent

such that Θ_μ^μ consists of three pieces (**asqtad** slightly more complicated: needs $du_0/d\beta$)

$$\frac{\Theta_G^{\mu\mu}(T)}{T^4} = R_\beta N_\tau^4 \Delta \langle \bar{S}_G \rangle \quad \text{where } \Delta \langle \mathcal{O} \rangle = \langle \mathcal{O} \rangle_{T=0} - \langle \mathcal{O} \rangle_T$$

$$\frac{\Theta_F^{\mu\mu}(T)}{T^4} = -R_\beta R_m N_\tau^4 \{ 2\hat{m}_l \Delta \langle \bar{\psi} \psi \rangle_l + \hat{m}_s \Delta \langle \bar{\psi} \psi \rangle_s \}$$

$$\frac{\Theta_h^{\mu\mu}(T)}{T^4} = -R_\beta R_h N_\tau^4 \hat{m}_s \Delta \langle \bar{\psi} \psi \rangle_s$$

need: non-perturbative β functions $R_\beta(\beta)$, $R_m(\beta) = \frac{1}{\hat{m}_l(\beta)} \frac{d\hat{m}_l(\beta)}{d\beta}$

$$R_h(\beta) = \frac{1}{h(\beta)} \frac{dh(\beta)}{dh} = 0 \quad \text{at } h(\beta) = \frac{\hat{m}_l}{\hat{m}_s} = \text{const}$$

“action differences”

$$\Delta \bar{S}_G, \Delta \langle \bar{\psi} \psi \rangle_{l,s}$$

Simulation parameters

- $N_F = 2 + 1$: two degenerate u/d quarks + strange quark
- RHMC algorithm
- lattice sizes $T > 0$: $N_\sigma/N_\tau = 4$ $N_\tau = 4, 6, 8$ for $m_l/m_s = 1/10$ ($m_\pi \simeq 220$ MeV)
 $N_\tau = 8, 12$ for $m_l/m_s = 1/20$ ($m_\pi \simeq 150$ MeV)
- each $T > 0$ run accompanied by $T = 0$ run, for subtractions, scales
- $T = 0$: $N_\sigma/N_\tau \leq 1$ same N_σ as for $T > 0$
- statistics $\mathcal{O}(10k - 60k)$ for $T > 0$, each $(\beta, \hat{m}_l, \hat{m}_s)$
 $\mathcal{O}(5k)$ for $T = 0$, each $(\beta, \hat{m}_l, \hat{m}_s)$
- actions `p4fat3` on $N_\tau = 4, 6, 8$ both actions improve
`asqtad` on $N_\tau = 6, 8, 12$ – $\mathcal{O}((aT)^2)$ discretization effects and
– taste violations (present in all staggered actions)

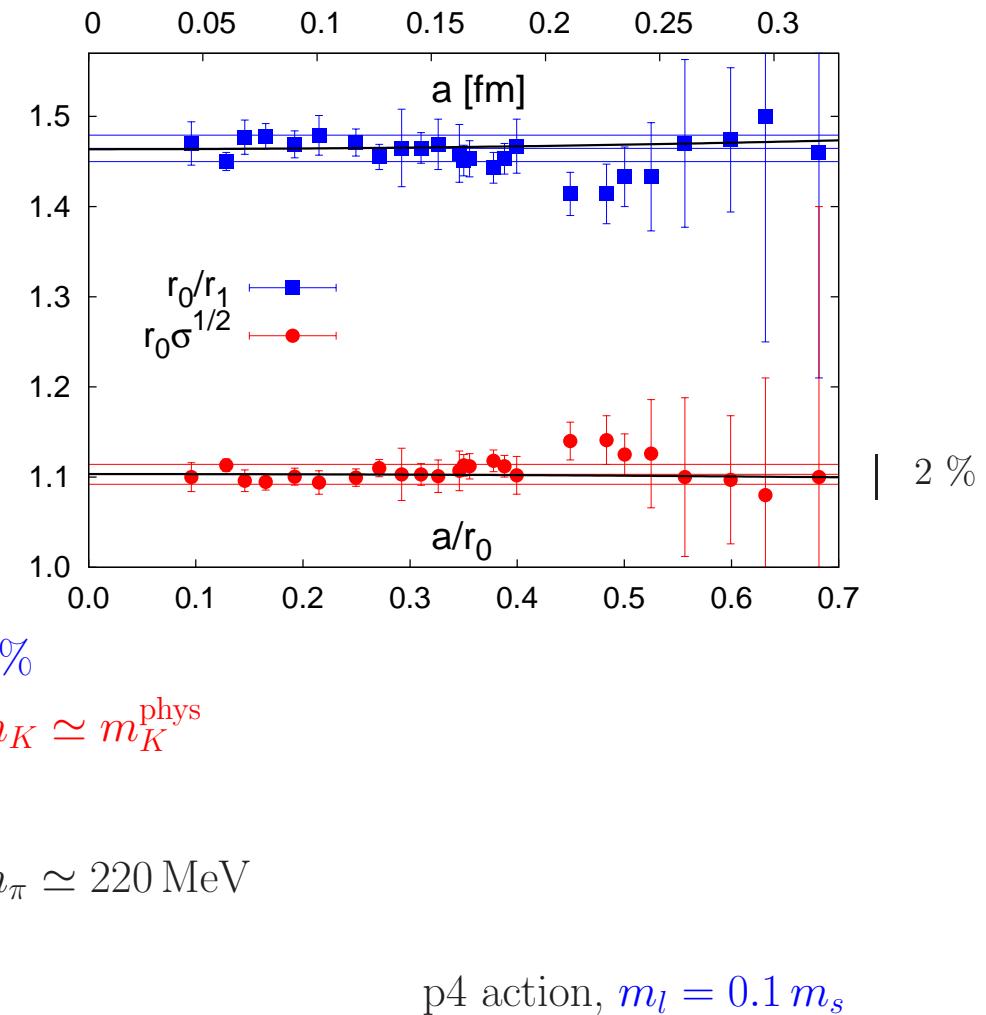

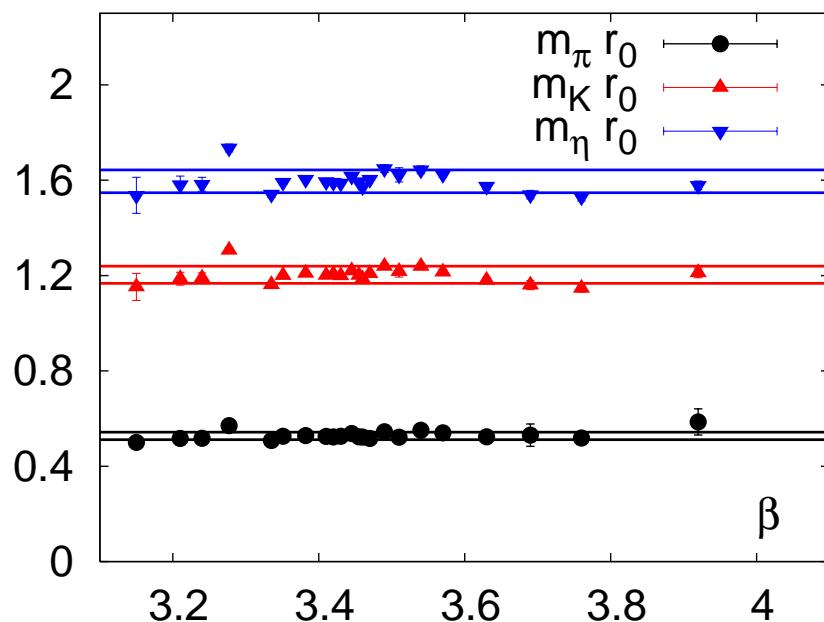

★ T = 0 scale taken from $\Upsilon 2S - 1S$ splitting [A. Gray et al.] via the heavy quark potential $V(r)$

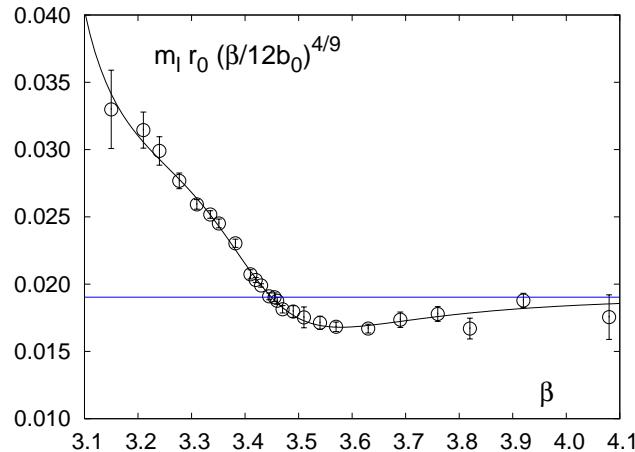

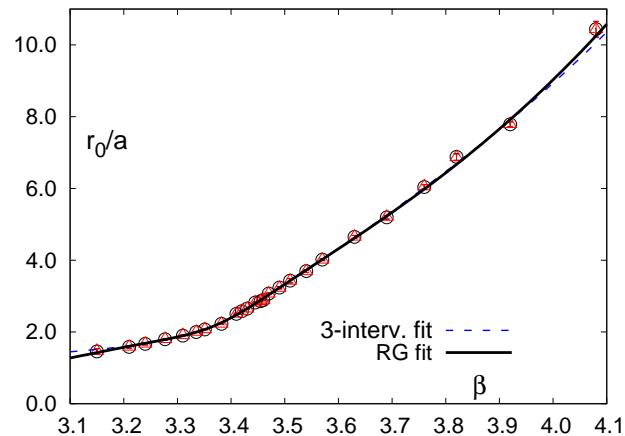

$$r_{0,1}/a \text{ from } r^2 \frac{dV(r)}{dr} \Big|_{r=r_{0,1}} = 1.65(1.0)$$

for absolute values (in MeV) we

use $r_0 = 0.469(7)$ fm [A. Gray et al.]

★ fine tune $\hat{m}_l(\beta)$

Allton inspired parametrization with rational fct. in $\hat{a}(\beta) = R_\beta^{(2-loop)}(\beta)/R_\beta^{(2-loop)}(\beta = 3.4)$

$$\frac{a}{r_0} = a_r R_\beta^{(2-loop)} \frac{1 + b_r \hat{a}^2 + c_r \hat{a}^4 + d_r \hat{a}^6}{1 + e_r \hat{a}^2 + f_r \hat{a}^4} \Rightarrow R_\beta = \frac{r_0}{a} \left(\frac{dr_0/a}{d\beta} \right)^{-1}$$

$$\hat{m}_l = a_m R_\beta^{(2-loop)} \left(\frac{12b_0}{\beta} \right)^{4/9} \frac{1 + b_m \hat{a}^2 + c_m \hat{a}^4 + d_m \hat{a}^6}{1 + e_m \hat{a}^2 + f_m \hat{a}^4 + g_m \hat{a}^6} \Rightarrow R_m$$

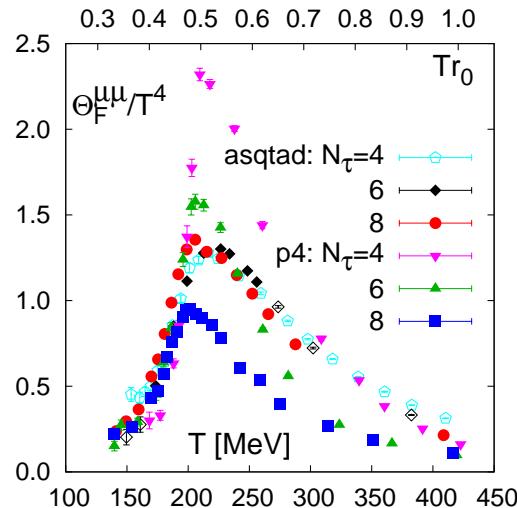

for asqtad there is a general parametrization for a large set of $T = 0$ data

results: $m_l = 0.1 m_s$

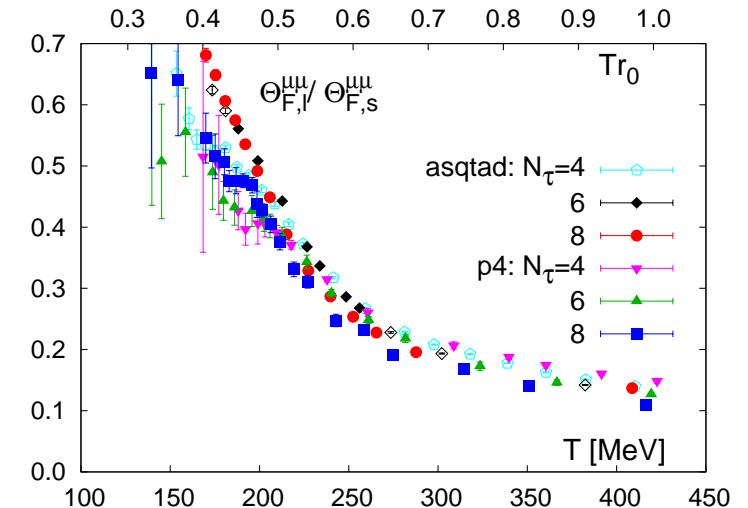

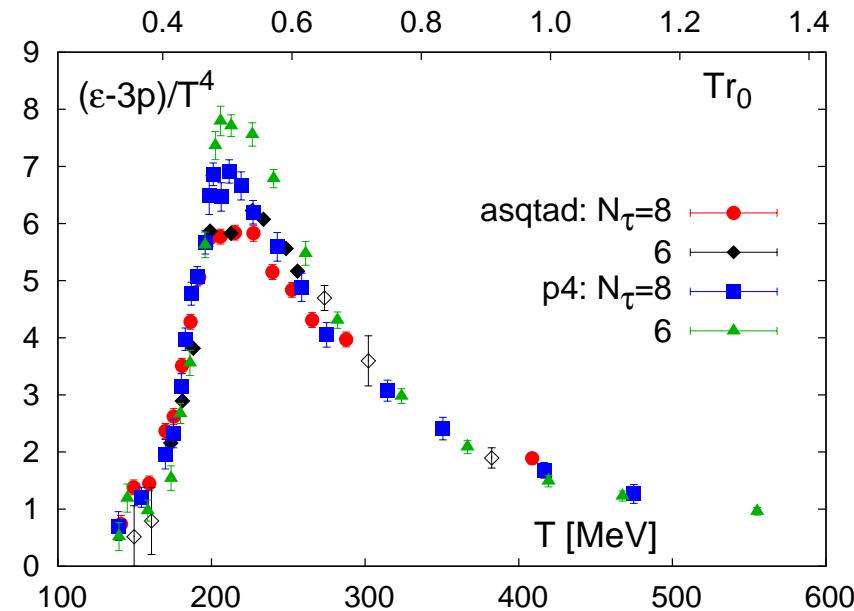

$\Theta_\mu^\mu(T)/T^4$ (the central quantity)

* very good agreement between
p4fat3 and asqtad actions

* except in the peak region, here differences dominantly due to fermionic part Θ_F

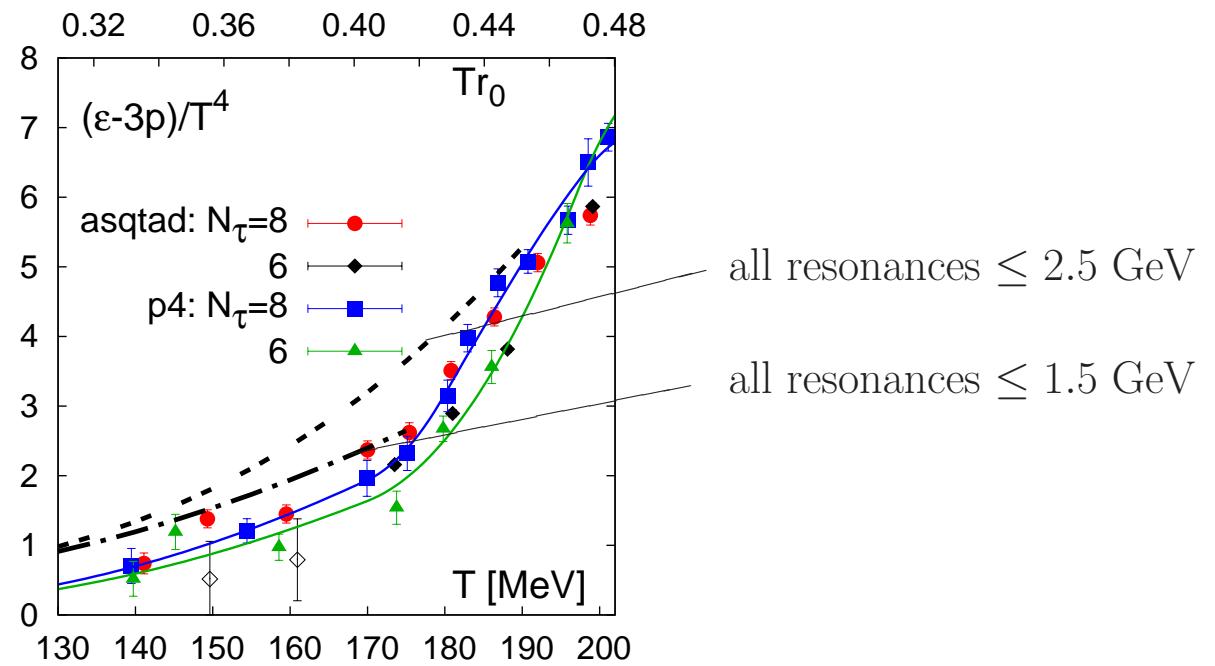

there: 15 % Θ_F contribution
 \Rightarrow 5 % overall
affected by R_m at low β
 \leadsto drops out in $\Theta_{F,l}/\Theta_{F,s}$
remaining differences due to
slight mismatch in m_s^{phys}

results $m_l = 0.1 m_s$
 low T region:

model to compare with:
 hadron resonance gas (HRG)

$$\left(\frac{\epsilon - 3p}{T^4}\right)_{low\ T} = \sum_{m_i \leq m_{max}} \frac{d_i}{2\pi^2} \sum_{k=1}^{\infty} (\pm)^{k+1} \frac{1}{k} \left(\frac{m_i}{T}\right)^3 K_1(km_i/T)$$

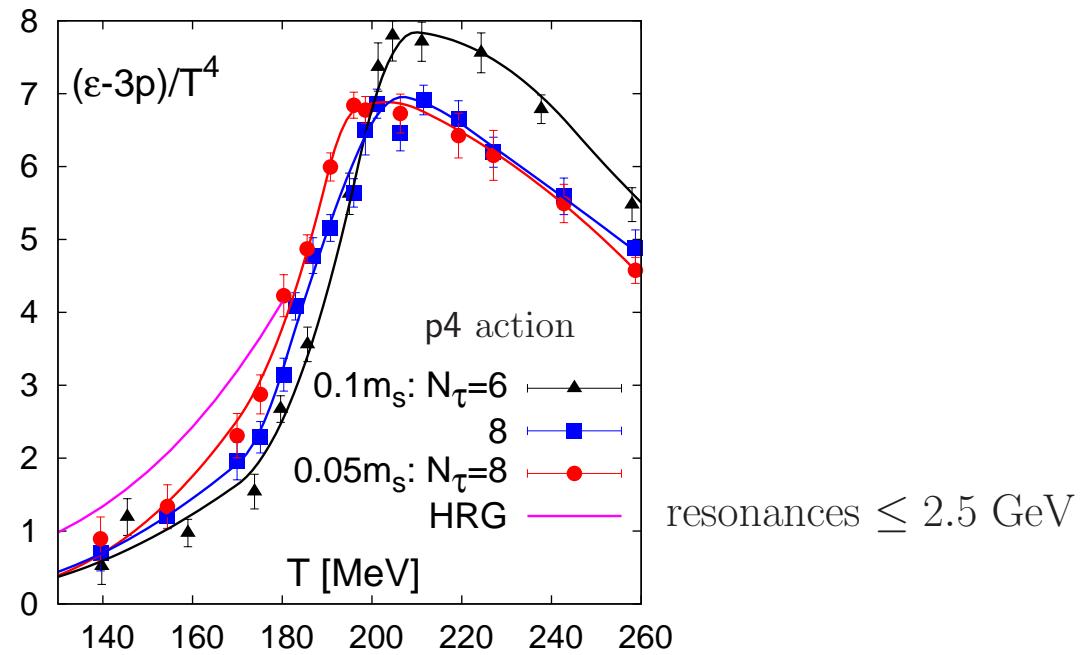

- ★ non-negligible contribution of heavy resonances in HRG
- ★ reducing discretization effects lowers the crossover temperature

results $m_l = 0.05 m_s$

low T region:

model to compare with:

hadron resonance gas (HRG)

$$\left(\frac{\epsilon - 3p}{T^4}\right)_{low\ T} = \sum_{m_i \leq m_{max}} \frac{d_i}{2\pi^2} \sum_{k=1}^{\infty} (\pm)^{k+1} \frac{1}{k} \left(\frac{m_i}{T}\right)^3 K_1(km_i/T)$$

- ★ reducing discretization effects lowers the crossover temperature
- ★ diminishing quark mass lowers the crossover temperature
- ★ smaller quark masses are expected to raise $\epsilon - 3p$ somewhat at low T

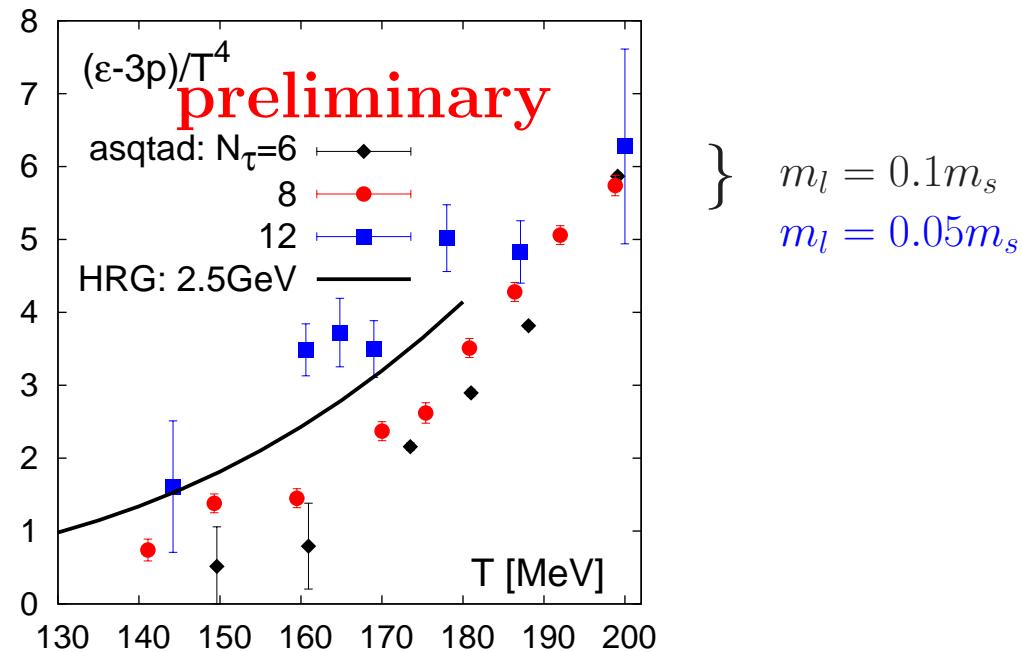

results

low T region:

$$N_\tau = 12, m_l = 0.05 m_s$$

model to compare with:

hadron resonance gas (HRG)

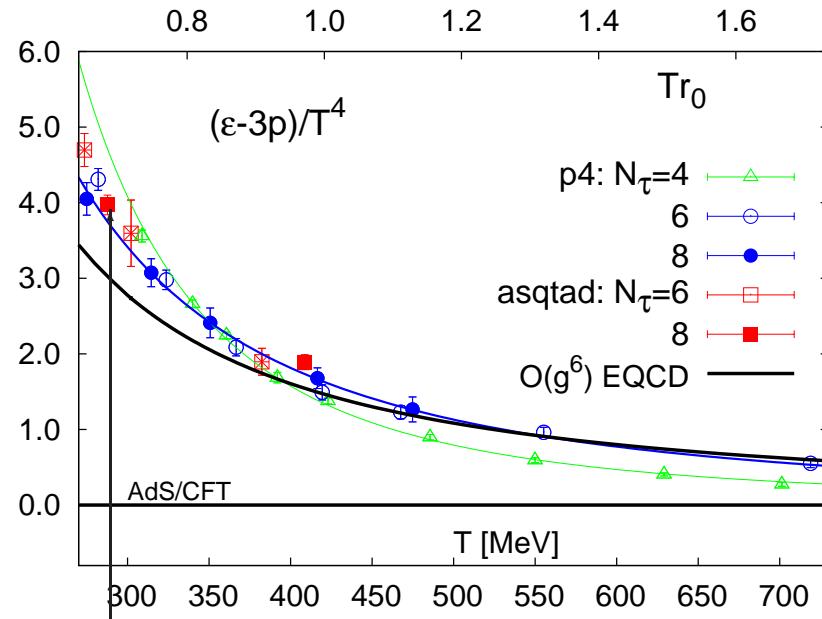

$$\left. \begin{array}{l} m_l = 0.1 m_s \\ m_l = 0.05 m_s \end{array} \right\}$$

$$\left(\frac{\epsilon - 3p}{T^4} \right)_{low T} = \sum_{m_i \leq m_{max}} \frac{d_i}{2\pi^2} \sum_{k=1}^{\infty} (\pm)^{k+1} \frac{1}{k} \left(\frac{m_i}{T} \right)^3 K_1(km_i/T)$$

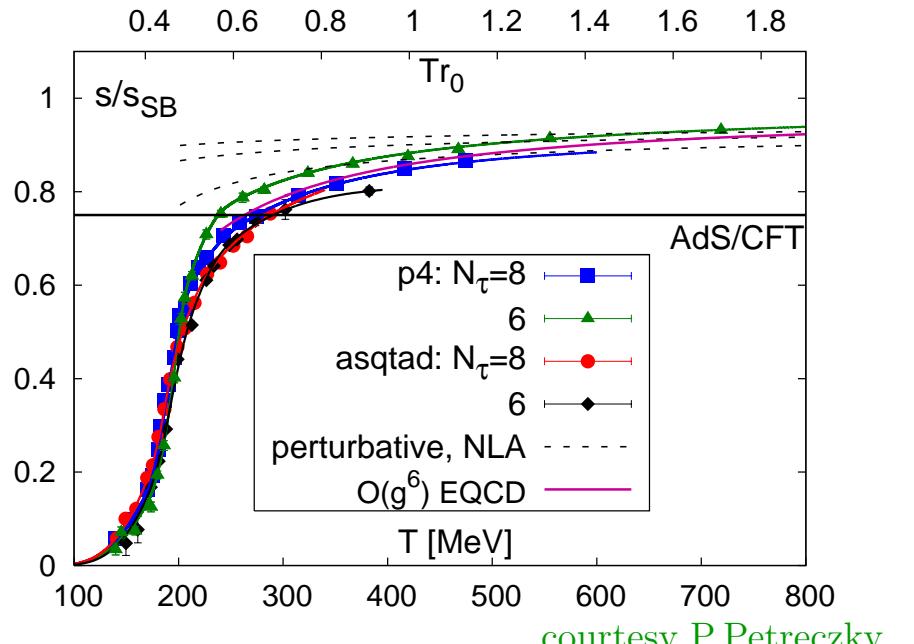

- ★ reducing discretization effects lowers the crossover temperature
- ★ diminishing quark mass lowers the crossover temperature
- ★ smaller quark masses are expected to raise $\epsilon - 3p$ somewhat at low T, but effect is small
- ★ reducing discretization effects from $N_\tau = 8 \rightarrow 12$ seems to raise $\epsilon - 3p$, **preliminary**

results: $m_l = 0.1 m_s$ high T

$$\left(\frac{\epsilon - 3p}{T^4}\right)_{high\,T} = \frac{3}{4}b_0g^4(T) + \frac{d_2}{T^2} + \frac{d_4}{T^4}$$

EQCD: 3d effective theory,
with perturbative matching to 4d
Kajantie et al.; Laine, Schröder

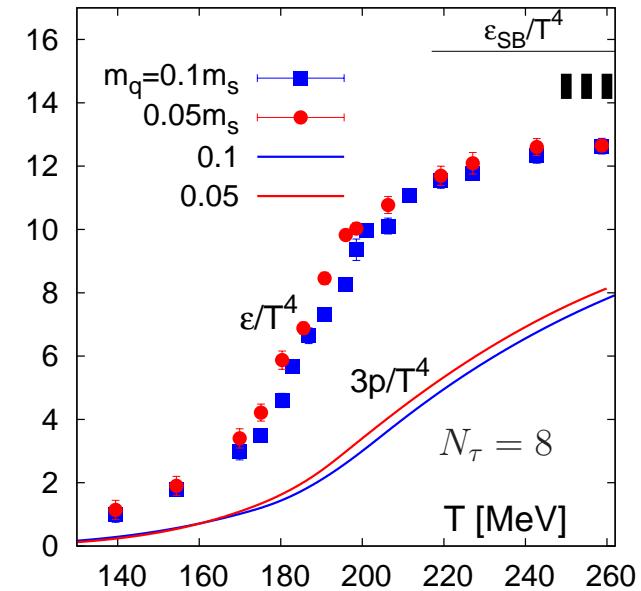

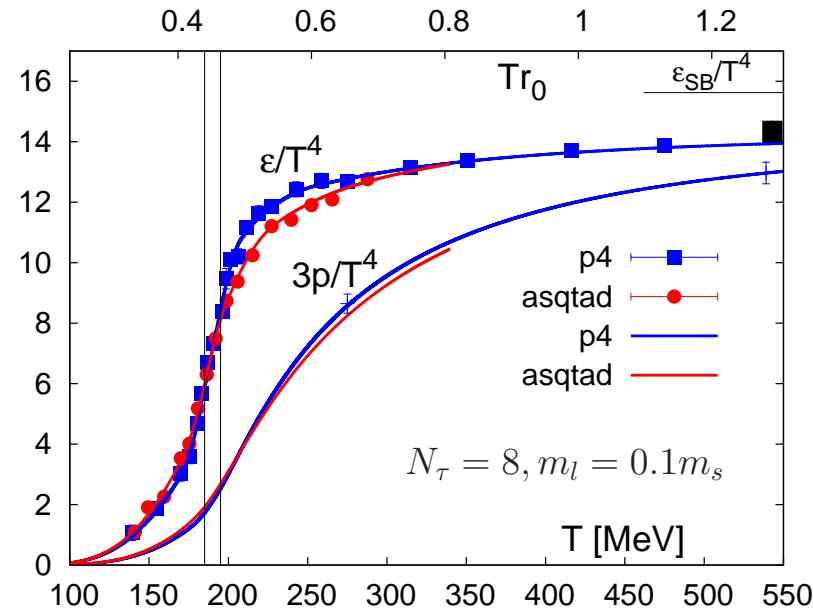

also agreement with resummed pert. theory

Blaizot et al.

results

pressure and energy density

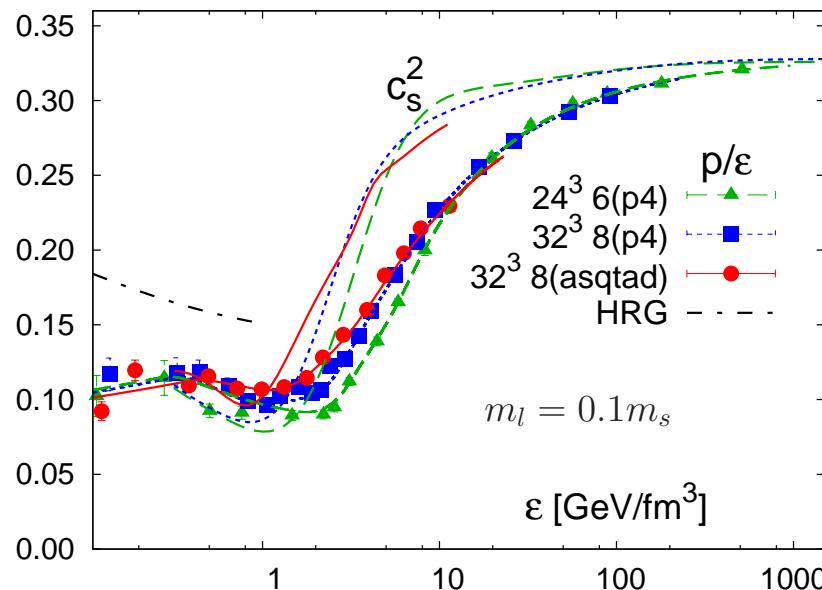

- * good agreement between **asqtad** and **p4fat3** actions
- * integration error: indicated by little bars to the right
- * in comparison with **Stefan-Boltzmann**: 10 % below at 2 - 3 T_c
- * quark mass effects negligible at high T

vertical lines denote $N_\tau = 8$ transition region $185 \text{ MeV} < T < 195 \text{ MeV}$ for $m_l = 0.1m_s$

results

speed of sound

$$c_s^2 = \frac{p}{\epsilon} + \epsilon \frac{d(p/\epsilon)}{d\epsilon}$$

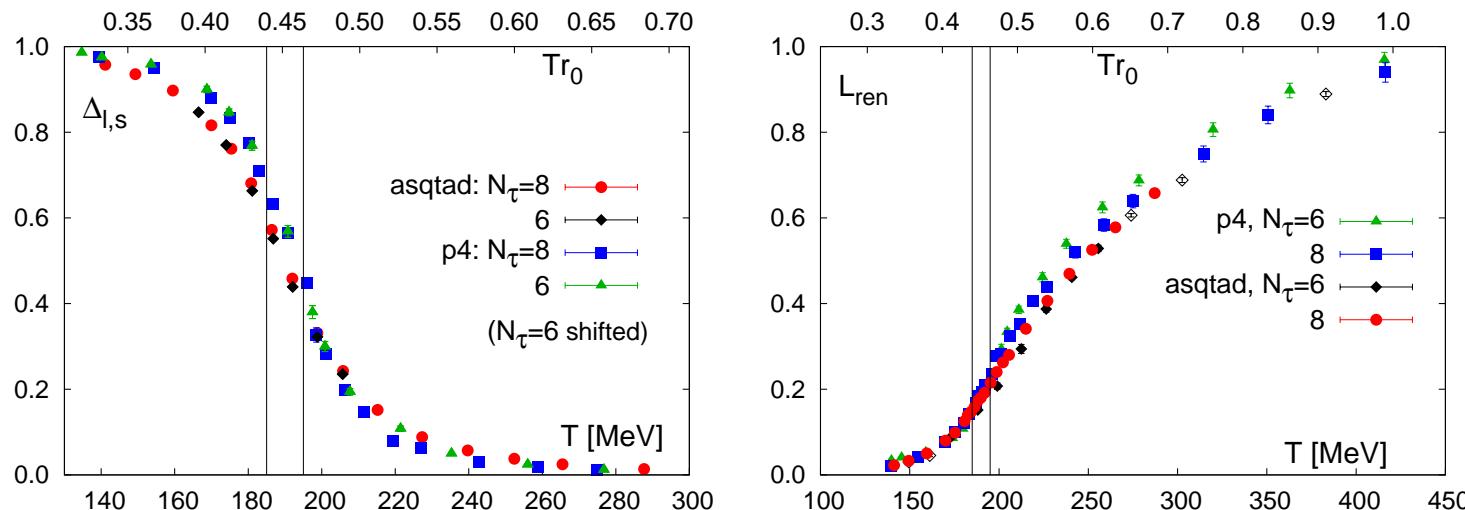

- ★ good agreement between **asqtad** and **p4fat3** actions
- ★ softest point corresponds to $\epsilon \simeq 1 \text{ GeV/fm}^3$

II Transition

comparison with chiral condensate and Polyakov loop

- chiral condensate $\langle \bar{\psi}\psi \rangle$ true order parameter in the chiral limit $m_q \rightarrow 0$
- Polyakov loop $L \sim \exp(-F_q/T)$ true order parameter in the static quark limit $m_q \rightarrow \infty$

- both need renormalization

$$\Delta_{l,s}(T) = \frac{\langle \bar{\psi}\psi \rangle_{l,T} - \frac{m_l}{m_s} \langle \bar{\psi}\psi \rangle_{s,T}}{\langle \bar{\psi}\psi \rangle_{l,0} - \frac{m_l}{m_s} \langle \bar{\psi}\psi \rangle_{s,0}}$$

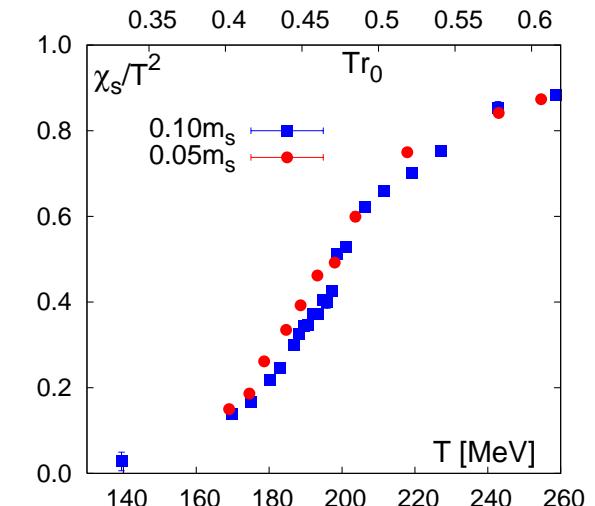

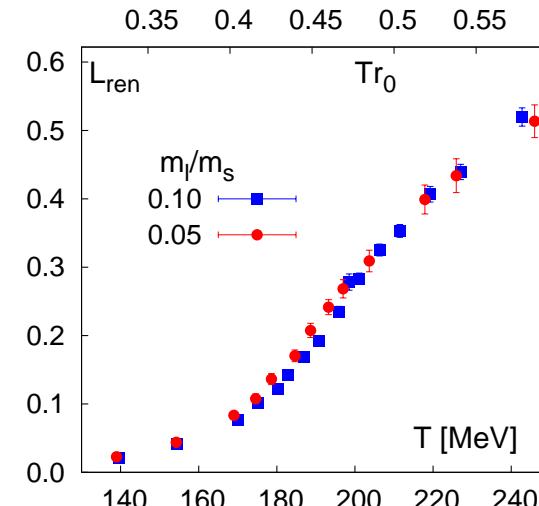

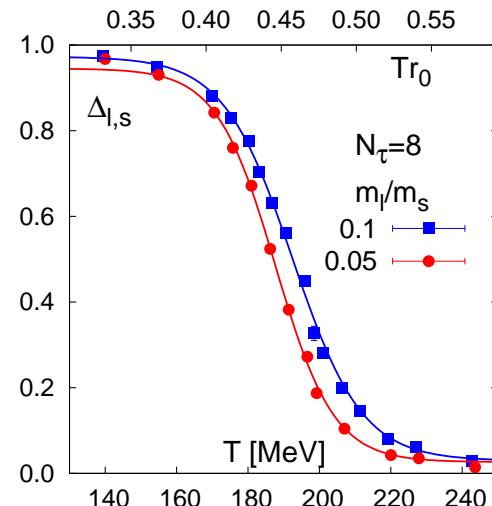

subtracting power-law additive and cancelling
multiplicative UV divergencies

UV renormalization via
normalization of static quark potential

significant changes in the same temperature range as EoS

going to $m_l = 0.05 m_s \leftrightarrow m_\pi \simeq 150$ MeV ($N_\tau = 8$, p4 action, asqtad $T = 0$ running)

strange quark number susceptibility

$$\chi_s(T) \sim \frac{1}{T^3 V} \left. \frac{\partial^2 \ln Z(T, \mu_s)}{\partial \mu_s^2} \right|_{\mu_s=0}$$

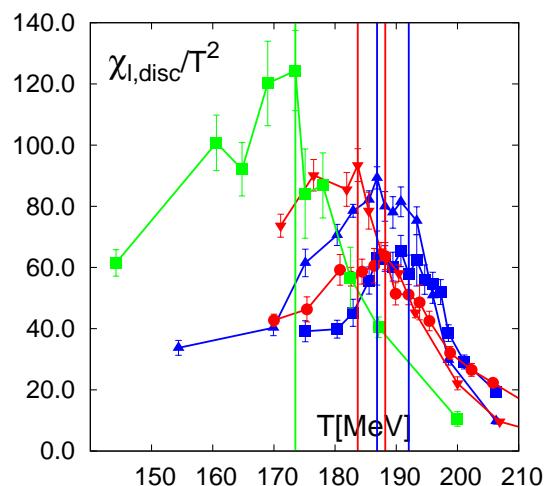

at low T : $\sim \exp(-m_K/T)$
not too sensitive to criticality

- as in EoS: overall shift by about -5 MeV due to smaller quark mass

going to $N_\tau = 12$ ($m_l = 0.05 m_s$, asqtad action)

disc. chiral susceptibility

$$\chi_{l,disc} \sim \langle (\bar{\psi}\psi)^2 \rangle_l - \langle \bar{\psi}\psi \rangle_l^2$$

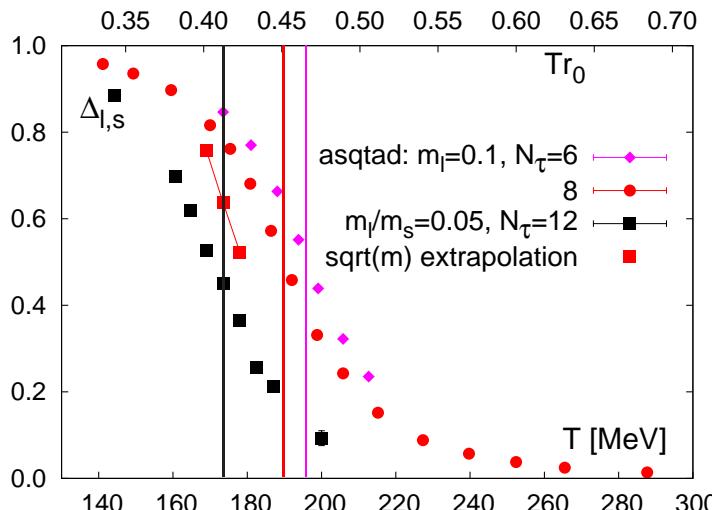

asqtad: $N_\tau = 8, N_\tau = 12$

p4: $N_\tau = 8$

vertical lines mark $\chi_{l,max}$

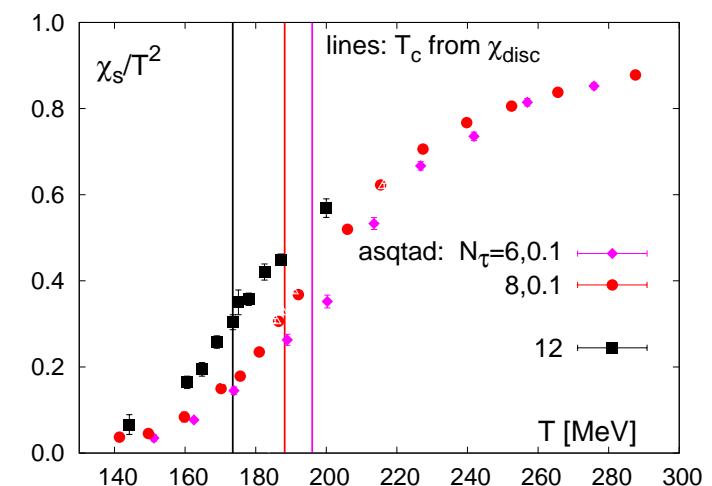

note the asymmetry around $\chi_{l,max}$

red boxes:

$N_\tau = 12$ at $m_l = 0.1 m_s$

through $\sqrt{m_l}$ extrapolation (see next section)

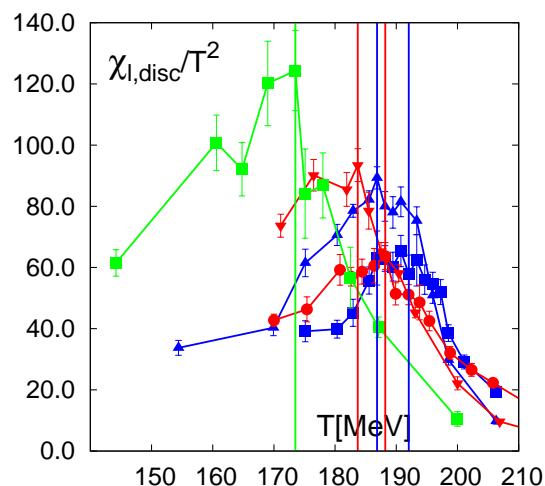

more work under way, so far:

- $\chi_{disc}, \Delta_{l,s}$ and χ_s simultaneously exhibit further downward shift in T
- suggesting a transition temperature $\lesssim 170$ MeV at physical π mass

going to $N_\tau = 12$ ($m_l = 0.05 m_s$, asqtad action)

disc. chiral susceptibility

$$\chi_{l,disc} \sim \langle (\bar{\psi}\psi)^2 \rangle_l - \langle \bar{\psi}\psi \rangle_l^2$$

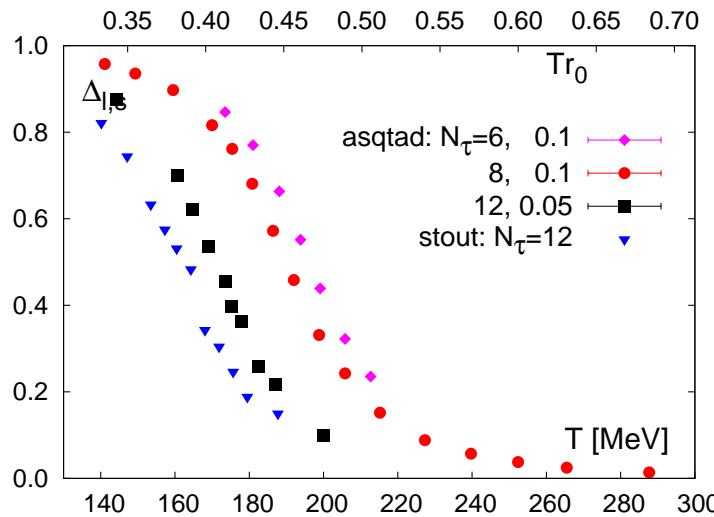

asqtad: $N_\tau = 8, N_\tau = 12$

p4: $N_\tau = 8$

vertical lines mark $\chi_{l,max}$

note the asymmetry around $\chi_{l,max}$

comparison with the stout action (Budapest-Wuppertal):

differences in the $\Delta_{l,s}, \chi_s$ data decrease with decreasing a

for a comparison with the hisq action see talk by P.Petreczky

- more work under way, so far:
- $\chi_{disc}, \Delta_{l,s}$ and χ_s simultaneously exhibit further downward shift in T
 - suggesting a transition temperature $\lesssim 170$ MeV at physical π mass

III Critical behavior ?!

phase diagram of QCD at $\mu_q = 0$

- chiral symmetry of 2 flavor QCD is:

$$SU_L(2) \times SU_R(2) \simeq O(4)$$

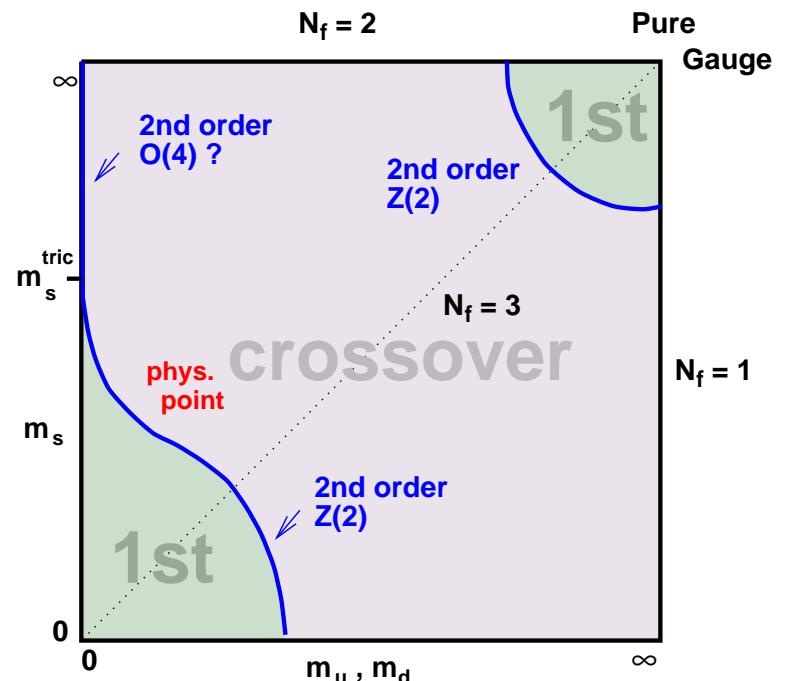

- hence, if m_s is large enough in 2+1 QCD

expect universal behavior as of 3d $O(4)$ spins
in the vicinity of finite T chiral limit, $m_l \rightarrow 0$

[Pisarski, Wilczek, ...]

- so far no clear evidence from numerical simulations
and there are caveats due to the fate of the $U_A(1)$
[long list of refs.]

- staggered fermions preserve a flavor non-diagonal $U(1)$ part of chiral symmetry even at $a > 0$
 \Rightarrow search for $O(2)$ critical behavior in the vicinity of chiral limit also at $a > 0$

magnetic equation of state in $O(N)$ spin models

magnetization $M = h^{1/\delta} f_G(z)$

where $z = t/h^{1/\beta\delta}$

$f_G(z)$ universal scaling function

$$t = \frac{1}{t_0} \frac{T - T_c}{T_c} \quad \text{reduced temperature}$$

$$h = \frac{H}{h_0} \quad \text{external field}$$

β, δ universal critical exponents

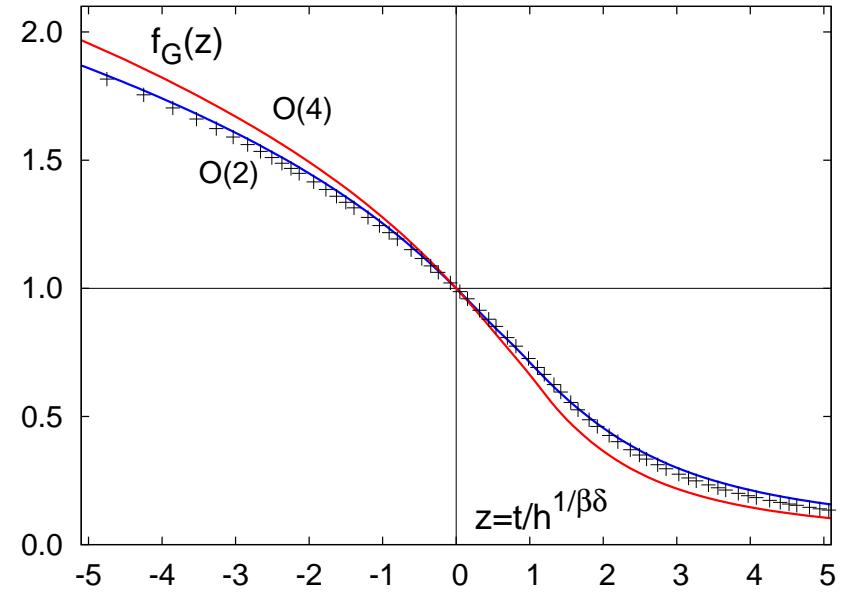

t_0, h_0 non-universal normalizations

$f_G(z), \beta, \delta$ known to high precision Engels et al., condensed matter literature

in the limit $z \rightarrow -\infty$, corresponding to $h \rightarrow 0$ and $t < 0$

$$f_G(z) \rightarrow (-z)^\beta \{1 + \tilde{c}_2(-z)^{-\beta\delta/2}\} \quad \text{corresponding to} \quad M(t, h) \rightarrow M(t, 0) + c_2(t)\sqrt{h}$$

Goldstone effect

note: difference between O(2) and O(4) tiny

magnetic equation of state in QCD

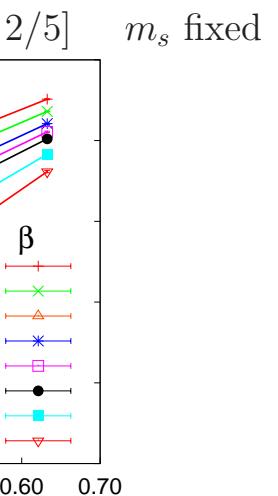

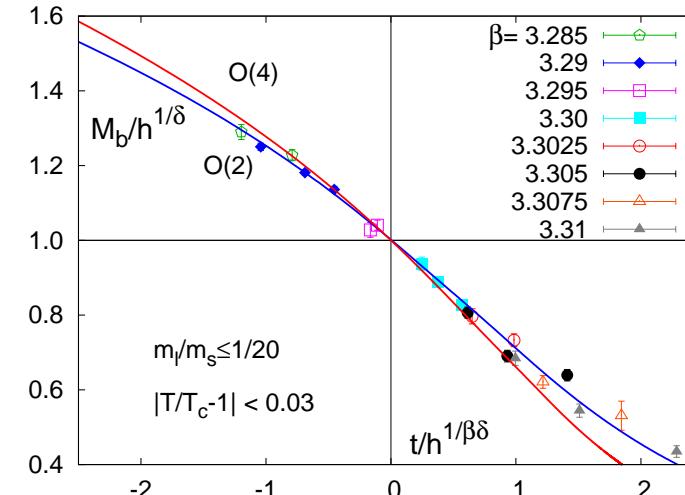

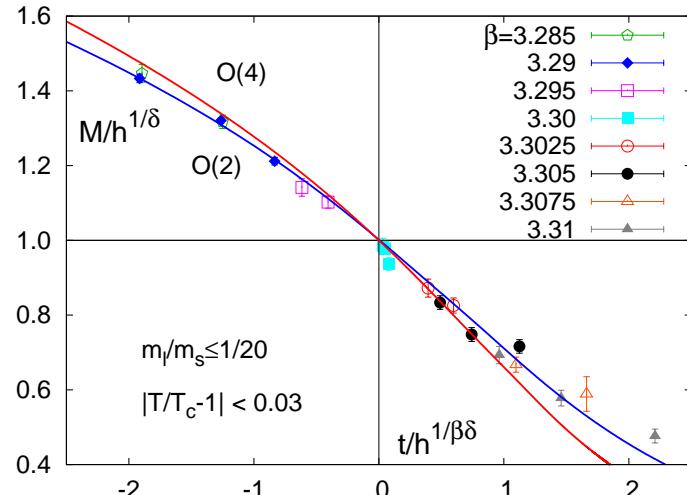

here $M \sim \langle \bar{\psi} \psi \rangle_l$ $H \sim m_l$

we use $M_b = m_s \langle \bar{\psi} \psi \rangle_l$

$$M = m_s \left[\langle \bar{\psi} \psi \rangle_l - \frac{m_l}{m_s} \langle \bar{\psi} \psi \rangle_s \right]$$

- ★ clear evidence for $\sqrt{m_l}$ dependence at low β
i.e. for Goldstone effect

- fit to the $O(2)$ scaling function $f_G(z)$, 3 fit parameters: $t_0, h_0, T_c(m_l = 0)$

consistency with $O(N)$ scaling behavior at small quark masses

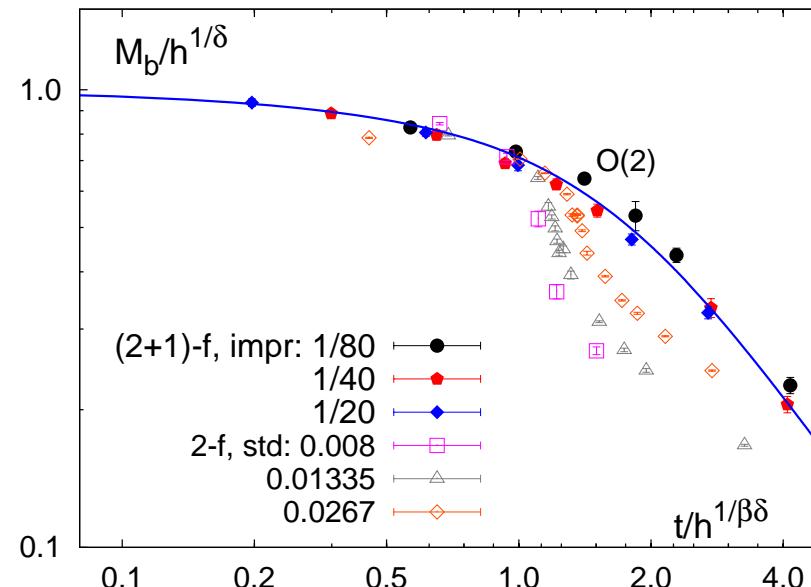

m_l/m_s	m_π
1/80	75 MeV
1/40	105 MeV
1/20	150 MeV

comparison to staggered data in the standard discretization

until now

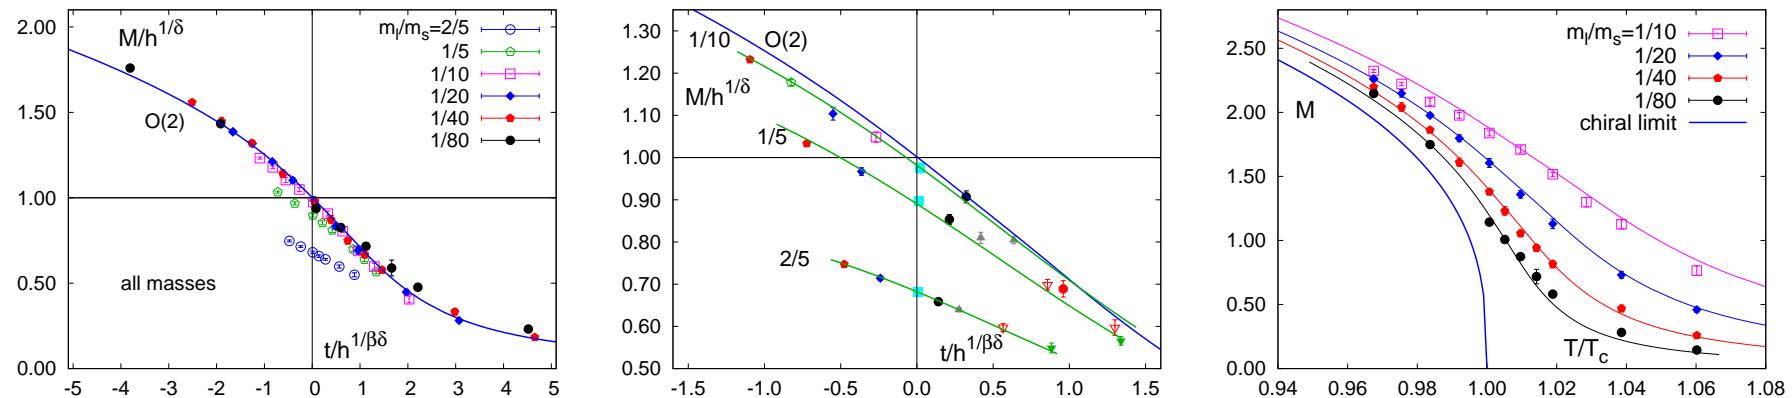

comparison with magn. EoS
for $z > 0$ only

similar difficulties with fits for
critical exponents

MILC, Pisa data

scaling violations

– are clearly visible in the region of small $|z|$ i.e. large m_l and small t , and can be parametrized as

$$M(t, h) = h^{1/\delta} f_G(t/h^{1/\beta\delta}) + a_t th + b_1 h + b_3 h^3 + b_5 h^5$$

since the scale parameters t_0, h_0 have been determined above

– for the linear term: $b_1 = 0$ for M (subtracted condensate)

$$b_1 \neq 0 \text{ for } M_b$$

→ curves and chiral extrapolation for $M(T)$

★ scaling violations are small for physical values of the quark mass

Summary

- Equation of State

- extending analysis to $m_\pi \simeq 150$ MeV on $N_\tau = 12$ lattices
- at low T : reducing lattice spacing and quark mass leads to approaching HRG
- at high T : making contact with (resummed) perturbation theory and EQCD

- Transition

- reducing a and m_l affects the studied observables in the same way,
- suggests a continuum extrapolated value of $T_c \lesssim 170$ MeV preliminary

- critical behavior ?

- finally, strong indications for $O(N)$ scaling of the magnetic equation of state !
- although at large lattice spacing, hints at physical point possibly being in the attraction basin of a second order chiral phase transition
- optimistic signal for further studies of the QCD phase diagram
